

ST7SCR

8-BIT LOW-POWER, FULL-SPEED USB MCU WITH 16K FLASH, 768 RAM, SMARTCARD I/F, TIMER

Memories

- Up to 16K of ROM or High Density Flash (HD-Flash) program memory with read/write protection, HDFlash In-Circuit and In-Application Programming 100 write leave cycles guarantees and the programming the progr teed, data retention: 40 years at 55°C
- Up to 768 bytes of RAM including up to 128 bytes stack and 256 bytes USB buffer

Clock, Reset and Supply Management

- Low Voltage Reset
- 2 power saving modes: Halt and Wait modes
- PLL for generating 48 MHz USB clock using a 4 MHz crystal

Interrupt Management

Nested Interrupt Controller

USB (Universal Serial Bus) Interface

- 256-byte buffer for full speed bulk, control and interrupt transfer types compliant with USB specification (version 2.0)
- On-Chip 3.3V USB voltage regulator an transceivers with software power down
 7 USB Endponts: One 8-byte Bidirectional Control Endpoint One 64-byte In Endpoint, One 64-byte Out Endpoint Four 8-byte In Endpoints

35 or 4 I/O ports

- Up to 4 LED outputs with software programmable constant current (3 or 7 mA).
- 2 General purpose I/Os programmable as interrupts
- Up to 8 line inputs programmable as interrupts
- Up to 20 Outputs
- 1 line assigned by default as static input after reset

SO24 QFN24 LQFP64 14x14

ISO7816-3 UART Interface

- 4 Mhz Clock generation
- Synchronous/Asynchronous protocols (T=0, T≟1)
- Automatic retry on parity error
- Programmable Baud rate from 372 clock pulses up to 11.625 clock pulses (D=32/F=372)
- Card Insertion/Removal Detection

Smartcard Power Supply

- Selectable card V_C (1.8V, 3√, and 5V
- Interna Sep-up converter for 5V supplied Smarcards (with a current of up to 55mA) using only two external components.
- Programmable Smartcard Internal Voltage Regulator (1.8V to 3.0V) with current overload protection and 4 KV ESD protection (Human Body Model) for all Smartcard Interface I/Os

One 8-bit Timer

 Time Base Unit (TBU) for generating periodic interrupts.

Development Tools

1 INTRODUCTION

The ST7SCR and ST7FSCR devices are members of the ST7 microcontroller family designed for USB applications. All devices are based on a common industry-standard 8-bit core, featuring an enhanced instruction set.

The ST7SCR ROM devices are factory-programmed and are not reprogrammable.

The ST7FSCR versions feature dual-voltage Flash memory with Flash Programming capability.

They operate at a 4MHz external oscillator frequency.

Under software control, all devices can be placed in WAIT or HALT mode, reducing power consumption when the application is in idle or stand-by state.

The enhanced instruction set and addressing modes of the ST7 offer both power and flexibility to software developers, enabling the design of highly efficient and compact application code. In addition to standard 8-bit data management, all ST7 microcontrollers feature true bit manipulation, 8x8 un-

signed multiplication and indirect addressing modes.

The devices include an ST7 Core, up to 16 Kbytes of program memory, up to 512 bytes of user RAM, up to 35 I/O lines and the following on-chip peripherals:

- USB full speed interface with 7 endpoints, programmable in/out configuration and embedded 3.3V voltage regulator and transceivers (no external components are needed).
- ISO7816-3 UART interface with Programmable Baud rate from 372 clock pulses up to 11.625 clock pulses
- Smartcard Supply Block able to provide programmable supply voltage and I/O voltage levels to the smartcards
- Low voltage reset ensuring proper power-on or power-off of the device (selectable by option)
- Watchdog Timer
- 8-bit Timer (TBU)

PIN DESCRIPTION

Figure 5. Smartcard Interface Reference Application - 24-Pin SO Package

Note 1: C1 and C2 must be located close to the chip.

Note 2: Refer to section 6 on page 21 & Section 14.4.3 Crystal Resonator Oscillators.

Figure 6. Smartcard Interface Reference Application - 64-Pin LQFP Package

Note 1: C1, C2, C7 and C8 must be located close to the chip.

Note 2: Refer to section 6 on page 21 & Section 14.4.3 Crystal Resonator Oscillators.

3 REGISTER & MEMORY MAP

As shown in Figure 7, the MCU is capable of addressing 64K bytes of memories and I/O registers.

The available memory locations consist of 40 bytes of register locations, up to 512 bytes of RAM and up to 16K bytes of user program memory. The RAM space includes up to 128 bytes for the stack from 0100h to 017Fh.

The highest address bytes contain the user reset and interrupt vectors.

IMPORTANT: Memory locations noted "Reserved" must never be accessed. Accessing a reserved area can have unpredictable effects on the device.

4 FLASH PROGRAM MEMORY

4.1 Introduction

The ST7 dual voltage High Density Flash (HD-Flash) is a non-volatile memory that can be electrically erased as a single block or by individual sectors and programmed on a Byte-by-Byte basis using an external V_{PP} supply.

The HDFlash devices can be programmed and erased off-board (plugged in a programming tool) or on-board using ICP (In-Circuit Programming) or IAP (In-Application Programming).

The array matrix organisation allows each sector to be erased and reprogrammed without affecting other sectors.

4.2 Main Features

- Three Flash programming modes:
 - Insertion in a programming tool. In this mode, all sectors including option bytes can be programmed or erased.
 - ICP (In-Circuit Programming). In this mode, all sectors including option bytes can be programmed or erased without removing the device from the application board.
 - IAP (In-Application Programming) In this mode, all sectors expert Sector 0, (an be programmed or practice without removing the device from the application beard and while the application is running.
- ICT (In-Circuit Testing) for downloading and executing user application test patterns in RAM
- Read-out protection
- Register Access Security System (RASS) to prevent accidental programming or erasing

4.3 Structure

The Flash memory is organised in sectors and can be used for both code and data storage.

Depending on the overall FLASH memory size in the microcontroller device, there are up to three user sectors (see Table 4). Each of these sectors can be erased independently to avoid unnecessary erasing of the whole Flash memory when only a partial erasing is required.

The first two sectors have a fixed size of 4 Kbytes (see Figure 8). They are mapped in the upper part of the ST7 addressing space so the reset and interrupt vectors are located in Sector 0 (F000h-FFFFh).

Table 4. Sectors available in FLASH devices

Flash Memory Size (bytes)	Available Sectors			
4K	Sector 0			
8K	Sectors 0,1			
> 8K	Sectors 0,1, 2			

Figure 8. Memory map and sector address

FLASH PROGRAM MEMORY (Cont'd)

4.4 ICP (In-Circuit Programming)

To perform ICP the microcontroller must be switched to ICC (In-Circuit Communication) mode by an external controller or programming tool.

Depending on the ICP code downloaded in RAM, Flash memory programming can be fully customized (number of bytes to program, program locations, or selection serial communication interface for downloading).

When using an STMicroelectronics or third-party programming tool that supports ICP and the specific microcontroller device, the user needs only to implement the ICP hardware interface on the application board (see Figure 9). For more details on the pin locations, refer to the device pinout description.

ICP needs six signals to be connected to the programming tool. These signals are:

- V_{SS}: device power supply ground
- V_{DD}: for reset by LVD
- OSCIN: to force the clock during power-up
- ICCCLK: ICC output serial clock pin
- ICCDATA: ICC input serial data pin
- V_{PP}: ICC mode selection and program IC.com/ST voltage.

If ICCCLK or ICCDATA are used for other purposes in the application, a serial resistor has to be implemented to avoid a conflict in case one of the other devices forces the signal level.

Note: To develop a custom programming tool, refer to the ST7 FLASH Programming and ICC Reference Manual which gives full details on the ICC protocol hardware and software.

4.5 IAP (In-Application Programming)

This mode uses a BootLoader program previously stored in Sector 0 by the user (in ICP mode or by plugging the device in a programming tool).

This mode is fully controlled by user software. This allows it to be adapted to the user application, (user-defined strategy for entering programming mode, choice of communications protocol used to fetch the data to be stored, etc.). For example, it is possible to download code from the USB interface and program it in the Flash. IAP mode can be used to program any of the Flash sectors except Sector 0. which is write/erase protected to allow recovery in case errors occur during the programming operation.

Figure 9. Typical ICF Interlace

FLASH PROGRAM MEMORY (Cont'd)

Note: If the ICCCLK or ICCDATA pins are only used as outputs in the application, no signal isolation is necessary. As soon as the Programming Tool is plugged to the board, even if an ICC session is not in progress, the ICCCLK and ICCDATA pins are not available for the application. If they are used as inputs by the application, isolation such as a serial resistor has to implemented in case another device forces the signal. Refer to the Programming Tool documentation for recommended resistor values.

4.6 Program Memory Read-out Protection

The read-out protection is enabled through an option bit.

For Flash devices, when this option is selected, the program and data stored in the Flash memory are protected against read-out (including a re-write protection). When this protection is removed by reprogramming the Option Byte, the entire Flash program memory is first automatically erased and the device can be reprogrammed.

Refer to the Option Byte description for more details.

4.7 Related Documentation

For details on Flash programming and ICC protocol, refer to the ST7 Flash Programming Reference Manual and to the ST7 ICC Protocol Reference Manual.

4.8 Register Description

FLASH CONTROL/STATUS REGISTER (FCSR)

Read/Write

Reset Value: 0000 0000 (00h)

7							0
0	0	0	0	0	0	0	0

This register is reserved for use by Programming Tool software. It controls the FLASH programming and erasing operations. For details on customizing FLASH programming methods and In-Circuit Testing, refer to the ST7 FLASH Programming and

WWW BDT I C Reference Manual ST

5 CENTRAL PROCESSING UNIT

5.1 INTRODUCTION

This CPU has a full 8-bit architecture and contains six internal registers allowing efficient 8-bit data manipulation.

5.2 MAIN FEATURES

- Enable executing 63 basic instructions
- Fast 8-bit by 8-bit multiply
- 17 main addressing modes (with indirect addressing mode)
- Two 8-bit index registers
- 16-bit stack pointer
- Low power HALT and WAIT modes
- Priority maskable hardware interrupts
- Non-maskable software/hardware interrupts

5.3 CPU REGISTERS

The 6 CPU registers shown in Figure 10 are not present in the memory mapping and are accessed by specific instructions.

Accumulator (A)

The Accumulator is an 8-bit general purpose register used to hold operands and the results of the arithmetic and logic calculations and to manipulate data.

Index Registers (X and Y)

These 8-bit registers are used to create effective addresses or as temporary storage areas for data manipulation. (The Cross-Assembler generates a precede instruction (PRE) to indicate that the following instruction refers to the Y register.)

The Y register is not affected by the interrupt automatic procedures.

Program Counter (PC)

The program counter is a 16-bit register containing the address of the next instruction to be executed by the CPU. It is made of two 8-bit registers PCL (Program Counter Low which is the LSB) and PCH (Program Counter High Which is the MSB).

Figure 10. CPU Walser W BD C COM S

CENTRAL PROCESSING UNIT (Cont'd)

Condition Code Register (CC)

Read/Write

Reset Value: 111x1xxx

The 8-bit Condition Code register contains the interrupt masks and four flags representative of the result of the instruction just executed. This register can also be handled by the PUSH and POP instructions.

These bits can be individually tested and/or controlled by specific instructions.

Arithmetic Management Bits

Bit 4 = **H** Half carry.

This bit is set by hardware when a carry occurs between bits 3 and 4 of the ALU during an ADD or ADC instructions. It is reset by hardware during the same instructions.

0: No half carry has occurred.

1: A half carry has occurred.

This bit is tested using the JRH or JRM instruction. The H bit is use us in BCD arithmetic subroutines.

Bit 2 = N Negative.

This bit is set and cleared by hardware. It is representative of the result sign of the last arithmetic, logical or data manipulation. It's a copy of the result 7th bit.

0: The result of the last operation is positive or null.

1: The result of the last operation is negative (i.e. the most significant bit is a logic 1).

This bit is accessed by the JRMI and JRPL instructions.

Bit $1 = \mathbf{Z} \ Zero$.

This bit is set and cleared by hardware. This bit indicates that the result of the last arithmetic, logical or data manipulation is zero.

- 0: The result of the last operation is different from zero
- 1: The result of the last operation is zero.

This bit is accessed by the JREQ and JRNE test instructions.

Bit 0 = **C** Carry/borrow.

This bit is set and cleared by hardware and software. It indicates an overflow or an underflow has occurred during the last arithmetic operation.

- 0: No overflow or underflow has occurred.
- 1: An overflow or underflow has occurred.

This bit is driven by the SCF and RCF instructions and tested by the JRC and JRNC instructions. It is also affected by the "bit test and branch", shift and rotate instructions.

Interrupt Management Bits

Bit 5,3 = **I1**, **I0** Interrupt

The combination of the I1 and I0 bits gives the current interrupt software priority.

Interrupt Spitivare Priority	l1	10
Level 0 (main)	1	0
Level 1	0	1
Level 2	0	0
Level 3 (= interrupt disable)	1	1

These two bits are set/cleared by hardware when entering in interrupt. The loaded value is given by the corresponding bits in the interrupt software priority registers (IxSPR). They can be also set/cleared by software with the RIM, SIM, IRET, HALT, WFI and PUSH/POP instructions.

See the interrupt management chapter for more details.

CENTRAL PROCESSING UNIT (Cont'd)

Stack Pointer (SP)

Read/Write

Reset Value: 017Fh

The Stack Pointer is a 16-bit register which is always pointing to the next free location in the stack. It is then decremented after data has been pushed onto the stack and incremented before data is popped from the stack (see Figure 11).

Since the stack is 256 bytes deep, the 8 most significant bits are forced by hardware. Following an MCU Reset, or after a Reset Stack Pointer instruction (RSP), the Stack Pointer contains its reset value (the SP7 to SP0 bits are set) which is the stack higher address.

The least significant byte of the Stack Pointer (called S) can be directly accessed by a LD instruction.

Note: When the lower limit is exceeded, the Stack Pointer wraps around to the stack upper limit, without indicating the stack overflow. The previously stored information is then overwritten and therefore lost. The stack also wraps in case of an underflow.

The stack is used to save the return address during a subroutine call and the CPU context during an interrupt. The user may also directly manipulate the stack by means of the PUSH and POP instructions. In the case of an interrupt, the PCL is stored at the first location pointed to by the SP. Then the other registers are stored in the next locations as shown in Figure 11

- When an interrupt is received, the SP is decremented and the context is pushed on the stack.
- On return from interrupt, the SP is incremented and the context is popped from the stack.

A subroutine call occupies two locations and an interrupt five locations in the stack area.

6 SUPPLY, RESET AND CLOCK MANAGEMENT

6.1 CLOCK SYSTEM

6.1.1 General Description

The MCU accepts either a 4MHz crystal or an external clock signal to drive the internal oscillator. The internal clock (f_{CPU}) is derived from the internal oscillator frequency (f_{OSC}), which is 4Mhz.

After reset, the internal clock (f_{CPU}) is provided by the internal oscillator (4Mhz frequency).

To activate the 48-MHz clock for the USB interface, the user must turn on the PLL by setting the PLL_ON bit in the MISCR4 register. When the PLL is locked, the LOCK bit is set by hardware.

The user can then select an internal frequency (f_{CPU}) of either 4 MHz or 8MHz by programming the CLK_SEL bit in the MISCR4 register (refer to MISCELLANEOUS REGISTERS section on page 39).

The PLL provides a signal with a duty cycle of 50 %.

The internal clock signal (f_{CPU}) is also routed to the on-chip peripherals. The CPU clock signal consists of a square wave with a duty cycle of 50%.

Figure 12. Clock, Reset and Supply Block Diagram

The internal oscillator is designed to operate with an AT-cut parallel resonant quartz in the frequency range specified for $f_{\rm osc}$. The circuit shown in Figure 14 is recommended when using a crystal, and Table 5 lists the recommended capacitance. The crystal and associated components should be mounted as close as possible to the input pins in order to minimize output distortion and start-up stabilisation time. The LOCK bit in the MISCR4 register can also be used to generate the $f_{\rm CPU}$ directly from $f_{\rm OSC}$ if the PLL and the USB interface are not active.

Table 5. Recommended Values for 4 MHz Crystal Resonator

R _{SMAX}	20 Ω	25 Ω	70 Ω
C _{OSCIN}	56pF	47pF	22pF
C _{OSCOUT}	56pF	47pF	22pF

Note: R_{SMAX} is the equivalent serial resistor of the crystal (see crystal specification).

CLOCK SYSTEM (Cont'd)

6.1.2 External Clock

An external clock may be applied to the OSCIN input with the OSCOUT pin not connected, as shown on Figure 13.

Figure 13. .External Clock Source Connections

Figure 14. Crystal Resonator

6.2 RESET SEQUENCE MANAGER (RSM)

6.2.1 Introduction

The reset sequence manager has two reset sources:

- Internal LVD reset (Low Voltage Detection) which includes both a power-on and a voltage drop reset
- Internal watchdog reset generated by an internal watchdog counter underflow as shown in Figure 16.

6.2.2 Functional Description

The reset service routine vector is fixed at addresses FFFEh-FFFFh in the ST7 memory map.

The basic reset sequence consists of 3 phases as shown in Figure 15:

 A first delay of 30µs + 127 t_{CPU} cycles during which the internal reset is maintained.

- A second delay of 512 t_{CPU} cycles after the internal reset is generated. It allows the oscillator to stabilize and ensures that recovery has taken place from the Reset state.
- Reset vector fetch (duration: 2 clock cycles)

Low Voltage Detector

The low voltage detector generates a reset when $V_{DD} < V_{IT+}$ (rising edge) or $V_{DD} < V_{IT-}$ (falling edge), as shown in Figure 15.

The LVD filters spikes on V_{DD} larger than $t_{g(VDD)}$ to avoid parasitic resets. See "SUPPLY AND RESET CHARACTERISTICS" on page 81.

Note: It is recommended to make sure that the V_{DD} supply voltage rises monotonously when the device is exiting from Reset, to ensure the application functions properly.

7 INTERRUPTS

7.1 INTRODUCTION

The CPU enhanced interrupt management provides the following features:

- Hardware interrupts
- Software interrupt (TRAP)
- Nested or concurrent interrupt management with flexible interrupt priority and level management:
 - Up to 4 software programmable nesting levels
 - Up to 16 interrupt vectors fixed by hardware
 - 3 non maskable events: RESET, TRAP, TLI

This interrupt management is based on:

- Bit 5 and bit 3 of the CPU CC register (I1:0),
- Interrupt software priority registers (ISPRx),
- Fixed interrupt vector addresses located at the high addresses of the memory map (FFE0h to FFFFh) sorted by hardware priority order.

This enhanced interrupt controller guarantees full upward compatibility with the standard (not nested) CPU interrupt controller.

7.2 MASKING AND PROCESSING FLOW

The interrupt masking smaraged by the I and IC bits of the CC register and the ICP Ax registers which give the interrupt software priority level of each interrupt vector (see Table 6). The processing flow is shown in Figure 17.

When an interrupt request has to be serviced:

- Normal processing is suspended at the end of the current instruction execution.
- The PC, X, A and CC registers are saved onto the stack.
- I1 and I0 bits of CC register are set according to the corresponding values in the ISPRx registers of the serviced interrupt vector.
- The PC is then loaded with the interrupt vector of the interrupt to service and the first instruction of the interrupt service routine is fetched (refer to "Interrupt Mapping" table for vector addresses).

The interrupt service routine should end with the IRET instruction which causes the contents of the saved registers to be recovered from the stack.

Note: As a consequence of the IRET instruction, the I1 and I0 bits will be restored from the stack and the program in the previous level will resume.

Table 6. Interrupt Software Priority Levels

Interrupt software priority	Level	l1	10
Level 0 (main)	Low	1	0
evel 1	1	0	1
Level 2	- ◀	0	0
Level 3 (Interrupt disable)	High	1	1

Servicing Pending Interrupts

As several interrupts can be pending at the same time, the interrupt to be taken into account is determined by the following two-step process:

- the highest software priority interrupt is serviced,
- if several interrupts have the same software priority then the interrupt with the highest hardware priority is serviced first.

Figure 18 describes this decision process.

Figure 18. Priority Decision Process

When an interrupt request is not serviced immediately, it is latched and then processed when its software priority combined with the hardware priority becomes the highest one.

Note 1: The hardware priority is exclusive while the software one is not. This allows the previous process to succeed with only one interrupt.

Note 2: RESET, TRAP and TLI can be considered as having the highest software priority in the decision process.

Different Interrupt Vector Sources

Two interrupt source types are managed by the CPU interrupt controller: the non-maskable type (RESET, TLI, TRAP) and the maskable type (external or from internal peripherals).

Non-Maskable Sources

These sources are processed regardless of the state of the I1 and I0 bits of the CC register (see Figure 17). After stacking the PC, X, A and CC registers (except for RESET), the corresponding vector is loaded in the PC register and the I1 and I0 bits of the CC are set to disable interrupts (level 3). These sources allow the processor to exit HALT mode.

■ TLI (Top Level Hardware Interrupt)

This hardware interrupt occurs when a specific edge is detected on the dedicated TLI pin.

Caution: A TRAP instruction must not be used in a TLI service routine.

■ TRAP (Non Maskable Software Interrupt)

This software interrupt is serviced when the TRAP instruction is executed. It will be serviced according to the flowchart in Figure 17 as a TLI.

Caution: TRAP can be interrupted by a TLI.

■ RESET

The RESET source has the highest priority in the CPU. This means that the first current routine has the highest software priority (level 3) and the highest hardware priority.

See the RESET chapter for more details.

Maskable Sources

Maskable interrupt vector sources can be serviced if the corresponding interrupt is enabled and if its own interrupt software priority (in ISPRx registers) is higher than the one currently being serviced (I1 and I0 in CC register). If any of these two conditions is false, the interrupt is latched and thus remains pending

External interrupts allow the processor to exit from HALT low power mode.

External interrupt sensitivity is software selectable through the MISCR3 register.

External interrupt triggered on edge will be latched and the interrupt request automatically cleared upon entering the interrupt service routine.

If several input pins of a group connected to the same interrupt line are selected simultaneously, these will be logically NANDed.

Peripheral Interrupts

Usually the peripheral interrupts cause the Device to exit from HALT mode except those mentioned in the "Interrupt Mapping" table.

A peripheral interrupt occurs when a specific flag is set in the peripheral status registers and if the corresponding enable bit is set in the peripheral control register.

The general sequence for clearing an interrupt is based on an access to the status register followed by a read or write to an associated register.

Note: The clearing sequence resets the internal latch. A pending interrupt (i.e. waiting for being serviced) will therefore be lost if the clear sequence is executed.

7.3 INTERRUPTS AND LOW POWER MODES

All interrupts allow the processor to exit the WAIT low power mode. On the contrary, only external and other specified interrupts allow the processor to exit from the HALT modes (see column "Exit from HALT" in "Interrupt Mapping" table). When several pending interrupts are present while exiting HALT mode, the first one serviced can only be an interrupt with exit from HALT mode capability and it is selected through the same decision process shown in Figure 18.

Note: If an interrupt, that is not able to Exit from HALT mode, is pending with the highest priority when exiting HALT mode, this interrupt is serviced after the first one serviced.

7.4 CONCURRENT & NESTED MANAGEMENT

The following Figure 19 and Figure 20 show two different interrupt management modes. The first is called concurrent mode and does not allow an interrupt to be interrupted, unlike the nested mode in Figure 20. The interrupt hardware priority is given in this order from the lowest to the highest: MAIN, IT4, IT3, IT2, IT1, IT0, TLI. The software priority is given for each interrupt.

Warning: A stack overflow may occur without notifying the software of the failure.

Figure 19. Concurrent Interrupt Management

Figure 20. Nested Interrupt Management

7.5 INTERRUPT REGISTER DESCRIPTION CPU CC REGISTER INTERRUPT BITS

Read/Write

Reset Value: 111x 1010 (xAh)

7							0
1	1	11	н	10	N	Z	С

Bit 5, 3 = **I1, I0** Software Interrupt Priority

These two bits indicate the current interrupt software priority.

Interrupt Software Priority	Level	I1	10
Level 0 (main)	Low	1	0
Level 1		0	1
Level 2	\ \ \	0	0
Level 3 (= interrupt disable*)	High	1	1

These two bits are set/cleared by hardware when entering in interrupt. The loaded value is given by the corresponding bits in the interrupt software priority registers (ISPRx).

They can be also set/cleared by software with the RIM, SIM, HALT, WIF, IRET and PCSH/DOP instructions (see Interrupt Dedicated Instruction Set" table).

*Note: TLI, TRAP and RESET events can interrupt a level 3 program.

INTERRUPT SOFTWARE PRIORITY REGISTERS (ISPRX)

Read/Write (bit 7:4 of ISPR3 are read only)

Reset Value: 1111 1111 (FFh)

	1							0
ISPR0	I1_3	10_3	l1_2	10_2	l1_1	10_1	I1_0	10_0
ISPR1	11_7	10_7	I1_6	10_6	I1_5	10_5	l1_4	10_4
ISPR2	l1_11	10_11	l1_10	10_10	I1_9	10_9	I1_8	10_8
ISPR3	1	1	1	1	l1_13	10_13	l1_12	10_12

These four registers contain the interrupt software priority of each interrupt vector.

Each interrupt vector (except RESET and TRAP)
has corresponding bits in these registers where
its own software priority is stored. This correspondance is shown in the following table.

Vector address	ISPRx bits
FFFBh-FFFAh	I1_0 and I0_0 bits*
FFCsh cTF90	I1_1 and I0_1 bits
	<u> </u>
FFE1h-FFE0h	I1_13 and I0_13 bits

- Each I1_x and I0_x bit value in the ISPRx registers has the same meaning as the I1 and I0 bits in the CC register.
- Level 0 can not be written (I1_x=1, I0_x=0). In this case, the previously stored value is kept. (example: previous=CFh, write=64h, result=44h)

The RESET, TRAP and TLI vectors have no software priorities. When one is serviced, the I1 and I0 bits of the CC register are both set.

*Note: Bits in the ISPRx registers which correspond to the TLI can be read and written but they are not significant in the interrupt process management.

Caution: If the I1_x and I0_x bits are modified while the interrupt x is executed the following behaviour has to be considered: If the interrupt x is still pending (new interrupt or flag not cleared) and the new software priority is higher than the previous one, the interrupt x is re-entered. Otherwise, the software priority stays unchanged up to the next interrupt request (after the IRET of the interrupt x).

Table 7. Dedicated Interrupt Instruction Set

Instruction	New Description	Function/Example	l1	Н	10	N	Z	С
HALT	Entering Halt mode		1		0			
IRET	Interrupt routine return	Pop CC, A, X, PC	l1	Н	10	N	Z	С
JRM	Jump if I1:0=11	I1:0=11 ?						
JRNM	Jump if I1:0<>11	l1:0<>11 ?						
POP CC	Pop CC from the Stack	Mem => CC	l1	Н	10	N	Z	С
RIM	Enable interrupt (level 0 set)	Load 10 in I1:0 of CC	1		0			
SIM	Disable interrupt (level 3 set)	Load 11 in I1:0 of CC	1		1			
TRAP	Software trap	Software NMI	1		1			
WFI	Wait for interrupt		1		0			

Note: During the execution of an interrupt routine, the HALT, POPCC, RIM, SIM and WFI instructions change the current software priority up to the next IRET instruction or one of the previously mentioned instructions.

In order not to lose the current software priority level, the RIM, SIM, HALT, WFI and POP CC instructions should never be used in an interrupt routine.

Table 8. Interrupt Mapping

N°	Source Block	Description Description	Register Label	Priority Order	Exit from HA_T	Address Vector
	RESET V	(Asset)		Highest	y∈s	FFFEh-FFFFh
	TRAP	Software Interrupt	N/A	Priority		FFFCh-FFFDh
0	ICP	FLASH Start programming NMI interrupt (TLI)			no	FFFAh-FFFBh
1	UART	ISO7816-3 UART Interrupt	UIC		110	FFF8h-FFF9h
2	USB	USB Communication Interrupt	USBISTR			FFF6h-FFF7h
3	WAKUP1	External Interrupt Port C			yes	FFF4h-FFF5h
4	WAKUP2	External Interrupt Port A			yes	FFF2h-FFF3h
5	TIM	TBU Timer Interrupt	TBUSR		no	FFF0h-FFF1h
6	CARDDET 1)	Smartcard Insertion/Removal Interrupt 1)	USCUR		1400	FFEEh-FFEFh
7	ESUSP	End suspend Interrupt	USBISTR	▼	yes	FFECh-FFEDh
8	Not used			Lowest Priority	no	FFEAh-FFEBh

Note 1: This interrupt can be used to exit from USB suspend mode.

8 POWER SAVING MODES

8.1 INTRODUCTION

To give a large measure of flexibility to the application in terms of power consumption, two main power saving modes are implemented in the ST7.

After a RESET the normal operating mode is selected by default (RUN mode). This mode drives the device (CPU and embedded peripherals) by means of a master clock which is based on the main oscillator frequency.

From Run mode, the different power saving modes may be selected by setting the relevant register bits or by calling the specific ST7 software instruction whose action depends on the oscillator status.

8.2 WAIT MODE

WAIT mode places the MCU in a low power consumption mode by stopping the CPU.

This power saving mode is selected by calling the "WFI" ST7 software instruction.

All peripherals remain active. During WAIT mode, the I bit of the CC register is forced to 0, to enable all interrupts. All other registers and memor remain unchanged I had MCU remains in WAIT mode until an interrupt or Reset occurs where eupon the Program Counter branches to the starting address of the interrupt or Reset service routine. The MCU will remain in WAIT mode until a Reset or an Interrupt occurs, causing it to wake up.

Refer to Figure 21.

Figure 21. WAIT Mode Flow Chart

Note: Before servicing an interrupt, the CC register is pushed on the stack. The I-Bit is set during the interrupt routine and cleared when the CC register is popped.

POWER SAVING MODES (Cont'd)

8.3 HALT MODE

The HALT mode is the MCU lowest power consumption mode. The HALT mode is entered by executing the HALT instruction. The internal oscillator is then turned off, causing all internal processing to be stopped, including the operation of the on-chip peripherals.

Note: The PLL must be disabled before a HALT instruction

When entering HALT mode, the I bit in the Condition Code Register is cleared. Thus, any of the external interrupts (ITi or USB end suspend mode), are allowed and if an interrupt occurs, the CPU clock becomes active.

The MCU can exit HALT mode on reception of either an external interrupt on ITi, an end suspend mode interrupt coming from USB peripheral, or a reset. The oscillator is then turned on and a stabilization time is provided before releasing CPU operation. The stabilization time is 512 CPU clock cycles.

After the start up delay, the CPU continues operation by servicing the interrupt which wakes it up or by fetching the reset vector if a reset wakes it up.

www.BD

Figure 22. HALT Mode Flow Chart

Note: Before servicing an interrupt, the CC register is pushed on the stack. The I-Bit is set during the interrupt routine and cleared when the CC register is popped.

9 I/O PORTS

9.1 Introduction

The I/O ports offer different functional modes:

- transfer of data through digital inputs and outputs and for specific pins:
- alternate signal input/output for the on-chip peripherals.
- external interrupt detection

An I/O port is composed of up to 8 pins. Each pin can be programmed independently as digital input (with or without interrupt generation) or digital output.

9.2 Functional description

Each port is associated to 4 main registers:

- Data Register (DR)
- Data Direction Register (DDR)
- Option Register (OR)
- Pull Up Register (PU)

Each I/O pin may be programmed using the corresponding register bits in DDR register; bit X corresponding to pin X of the port. The same oprespondence is used for the DR register.

Table 9. I/O Pin Functions

DDR	MODE
0	Input
1	Output

Input Modes

The input configuration is selected by clearing the corresponding DDR register bit.

In this case, reading the DR register returns the digital value applied to the external I/O pin.

Note 1: All the inputs are triggered by a Schmitt trigger.

Note 2: When switching from input mode to output mode, the DR register should be written first to output the correct value as soon as the port is configured as an output.

Interrupt function

When an I/O is configured in Input with Interrupt, an event on this I/O can generate an external In-

terrupt request to the CPU. The interrupt sensitivity is given independently according to the description mentioned in the ITRFRE interrupt register.

Each pin can independently generate an Interrupt request.

Each external interrupt vector is linked to a dedicated group of I/O port pins (see Interrupts section). If more than one input pin is selected simultaneously as interrupt source, this is logically ORed. For this reason if one of the interrupt pins is tied low, it masks the other ones.

Output Mode

The pin is configured in output mode by setting the corresponding DDR register bit (see Table 7).

In this mode, writing "0" or "1" to the DR register applies this digital value to the I/O pin through the latch. Then reading the DR register returns the previously stored value.

Note: In this mode, the interrupt function is disabled.

Digital Alternate Function

When an or ochip peripheral sconfigured to use a pin, the alternate function is automatically selected. This alternate function takes priority over standard I/O programming. When the signal is coming from an on-chip peripheral, the I/O pin is automatically configured in output mode (push-pull or open drain according to the peripheral).

When the signal is going to an on-chip peripheral, the I/O pin has to be configured in input mode. In this case, the pin's state is also digitally readable by addressing the DR register.

Notes

- 1. Input pull-up configuration can cause an unexpected value at the input of the alternate peripheral input.
- When the on-chip peripheral uses a pin as input and output, this pin must be configured as an input (DDR = 0).

Warning: The alternate function must not be activated as long as the pin is configured as input with interrupt, in order to avoid generating spurious interrupts.

9.3 I/O Port Implementation

The hardware implementation on each I/O port depends on the settings in the DDR register and specific feature of the I/O port such as true open drain.

9.3.1 Port A

Table 10. Port A Description

12 ON-CHIP PERIPHERALS

12.1 WATCHDOG TIMER (WDG)

12.1.1 Introduction

The Watchdog timer is used to detect the occurrence of a software fault, usually generated by external interference or by unforeseen logical conditions, which causes the application program to abandon its normal sequence. The Watchdog circuit generates an MCU reset on expiry of a programmed time period, unless the program refreshes the counter's contents before the T6 bit becomes cleared.

12.1.2 Main Features

- Programmable free-running downcounter (64 increments of 65536 CPU cycles)
- Programmable reset
- Reset (if watchdog activated) when the T6 bit reaches zero
- Hardware Watchdog selectable by option byte
- Watchdog Reset indicated by status flag

If the watchdog is activated (the WDGA bit is set) and when the 7-bit timer (bits T[6:0]) rolls over from 40h to 3Fh (T6 becomes cleared), it initiates a reset cycle pulling low the reset pin for typically 500ns.

The application program must write in the CR register at regular intervals during normal operation to prevent an MCU reset. This downcounter is free-running: it counts down even if the watchdog is disabled. The value to be stored in the CR register must be between FFh and C0h (see Table 15):

- The WDGA bit is set (watchdog enabled)
- The T6 bit is set to prevent generating an immediate reset
- The T[5:0] bits contain the number of increments which represents the time delay before the watchdog produces a reset.

Table 15.Watchdog Timing (f_{CPU} = 8 MHz)

		Reg			W	DG timeout period (ms)
Max		FF	1	/		524.288
Min		CUI				8.192
	J	П	П			

12.1.3 Functional Description

The counter value stored in the CB register (bits T[6:0]), is decremented every 65,536 machine cycles, and the length of the timeout period can be programmed by the user in 64 increments.

Figure 27. Watchdog Block Diagram

WATCHDOG TIMER (Cont'd)

12.1.4 Software Watchdog Option

If Software Watchdog is selected by option byte, the watchdog is disabled following a reset. Once activated it cannot be disabled, except by a reset.

The T6 bit can be used to generate a software reset (the WDGA bit is set and the T6 bit is cleared).

12.1.5 Hardware Watchdog Option

If Hardware Watchdog is selected by option byte, the watchdog is always active and the WDGA bit in the CR is not used.

12.1.6 Low Power Modes

WAIT Instruction

No effect on Watchdog.

HALT Instruction

Halt mode can be used when the watchdog is enabled. When the oscillator is stopped, the WDG stops counting and is no longer able to generate a reset until the microcontroller receives an external interrupt or a reset.

If an external interrupt is received, the WDG restarts counting after 514 CPU clocks of the Software Watchard Aption, increase is gen of the Software Watchild aption, i are se erated, the WDG is disabled (reset state)

Recommendations

- Make sure that an external event is available to wake up the microcontroller from Halt mode.
- Before executing the HALT instruction, refresh the WDG counter, to avoid an unexpected WDG reset immediately after waking up the microcon-
- When using an external interrupt to wake up the microcontroller, reinitialize the corresponding I/O as Input before executing the HALT instruction. The main reason for this is that the I/O may be wrongly configured due to external interference or by an unforeseen logical condition.
- The opcode for the HALT instruction is 0x8E. To avoid an unexpected HALT instruction due to a program counter failure, it is advised to clear all

- occurrences of the data value 0x8E from memory. For example, avoid defining a constant in ROM with the value 0x8E.
- As the HALT instruction clears the I bit in the CC register to allow interrupts, the user may choose to clear all pending interrupt bits before executing the HALT instruction. This avoids entering other peripheral interrupt routines after executing the external interrupt routine corresponding to the wake-up event (reset or external interrupt).

12.1.7 Interrupts

None.

12.1.8 Register Description **CONTROL REGISTER (CR)**

Read/Write

Reset Value: 0111 1111 (7Fh)

7							0
WDGA	Т6	T5	T4	ТЗ	T2	T1	ТО

Bit 7 = WDGA Activation bit.

This bit is let by software and only cleared by hardware after a reset. When WDGA = 1, the watchdog can generate a reset.

0: Watchdog disabled

1: Watchdog enabled

Note: This bit is not used if the hardware watchdog option is enabled by option byte.

Bit 6:0 = T[6:0] 7-bit timer (MSB to LSB).

These bits contain the decremented value. A reset is produced when it rolls over from 40h to 3Fh (T6 becomes cleared).

12.2 TIME BASE UNIT (TBU)

12.2.1 Introduction

The Timebase unit (TBU) can be used to generate periodic interrupts.

12.2.2 Main Features

- 8-bit upcounter
- Programmable prescaler
- Period between interrupts: max. 8.1ms (at 8 MHz f_{CPU})
- Maskable interrupt

12.2.3 Functional Description

The TBU operates as a free-running upcounter.

When the TCEN bit in the TBUCSR register is set by software, counting starts at the current value of the TBUCV register. The TBUCV register is incremented at the clock rate output from the prescaler selected by programming the PR[2:0] bits in the TBUCSR register. When the counter rolls over from FFh to 00h, the OVF bit is set and an interrupt request is generated if ITE is set.

The user can write a value at any time in the TBUCV register.

12.2.4 Programming Example

In this example, timer is required to generate an interrupt after a delay of 1 ms.

Assuming that f_{CPU} is 8 MHz and a prescaler division factor of 256 will be programmed using the PR[2:0] bits in the TBUCSR register, 1 ms = 32 TBU timer ticks.

In this case, the initial value to be loaded in the TBUCV must be (256-32) = 224 (E0h).

Figure 28. TBU Block Diagram

TIMEBASE UNIT (Cont'd)

12.2.5 Low Power Modes

Mode	Description
WAIT	No effect on TBU
HALT	TBU halted.

12.2.6 Interrupts

Interrupt Event	Event Flag	Enable Control Bit	Exit from Wait	Exit from Halt
Counter Over- flow Event	OVF	ITE	Yes	No

Note: The OVF interrupt event is connected to an interrupt vector (see Interrupts chapter). It generates an interrupt if the ITE bit is set in the TBUCSR register and the I-bit in the CC register is reset (RIM instruction).

12.2.7 Register Description

TBU COUNTER VALUE REGISTER (TBUCV)

Read/Write

Reset Value: 0000 0000 (00h)

Bits 7:0 = CV[7:0] Counter Value

This register contains the 8-bit counter value which can be read and written anytime by software. It is continuously incremented by hardware if TCEN=1.

TBU CONTROL/STATUS REGISTER (TBUCSR)

Read/Write

Reset Value: 0000 0000 (00h)

7 0 0 0 OVF ITE TCEN PR2 PR1 PR0

Bits [7:6] = Reserved. Forced by hardware to 0.

Bit 5 = **OVF** Overflow Flag

This bit is set only by hardware, when the counter value rolls over from FFh to 00h. It is cleared by software reading the TBUCSR register. Writing to this bit does not change the bit value.

0: No overflow

1: Counter overflow

Bit 4 = **ITE** Interrupt enabled.

This bit is set and cleared by software.

0: Overflow interrupt disabled

1: Overflow interrupt enabled. An interrupt request is generated when OVF=1.

Bit 3 = TCEN TBU Enable.

This bit is set and cleared by so tware.

o: TBU counter is trozen and the prescaler is reset.

1: TBU counter and prescaler running.

Bits 2:0 = **PR[2:0]** Prescaler Selection

These bits are set and cleared by software to select the prescaling factor.

PR2	PR1	PR0	Prescaler Division Factor
0	0	0	2
0	0	1	4
0	1	0	8
0	1	1	16
1	0	0	32
1	0	1	64
1	1	0	128
1	1	1	256

12.3 USB INTERFACE (USB)

12.3.1 Introduction

The USB Interface implements a full-speed function interface between the USB and the ST7 microcontroller. It is a highly integrated circuit which includes the transceiver, 3.3 voltage regulator, SIE and USB Data Buffer interface. No external components are needed apart from the external pull-up on USBDP for full speed recognition by the USB host.

12.3.2 Main Features

- USB Specification Version 1.1 Compliant
- Supports Full-Speed USB Protocol
- Seven Endpoints (including default endpoint)
- CRC generation/checking, NRZI encoding/ decoding and bit-stuffing
- USB Suspend/Resume operations
- On-Chip 3.3V Regulator
- On-Chip USB Transceiver

12.3.3 Functional Description

The block diagram in Figure 29, gives an overview of the USB interface hardware.

For general information on the USB, refer to the "Universal Serial Bus Specifications" document available at http://:www.usb.org.

Serial Interface Engine

The SIE (Serial Interface Engine) interfaces with the USB, via the transceiver.

The SIE processes tokens, handles data transmission/reception, and handshaking as required by the USB standard. It also performs frame formatting, including CRC generation and checking.

Endpoints

The Endpoint registers indicate if the microcontroller is ready to transmit/receive, and how many bytes need to be transmitted.

Data Transfer to/from USB Data Buffer Memory

When a token for a valid Endpoint is recognized by the USB interface, the related data transfer takes place to/from the USB data buffer. At the end of the transaction, an interrupt is generated.

Interrupts

By reading the Interrupt Status register, application software can know which USB event has occurred.

USB Endpoint RAM Buffers

There are seven Endpoints including one bidirectional control Endpoint (Endpoint 0), five IN Endpoints (Endpoint 1, 2, 3, 4, 5) and one OUT endpoint (Endpoint 2).

Endpoint 0 is 2 x 8 bytes in size, Endpoint 1, 3, 4, and Endpoint 5 are 8 bytes in size and Endpoint 2 is 2×64 bytes in size.

Figure 30. Endpoint Buffer Size

12.3.4 Register Description INTERRUPT STATUS REGISTER (USBISTR)

Read/Write

Reset Value: 0000 0000 (00h)

7 0

CTR 0 SOVR ERROR SUSP ESUSP RESET SOF

These bits cannot be set by software. When an interrupt occurs these bits are set by hardware. Software must read them to determine the interrupt type and clear them after servicing.

Note: The CTR bit (which is an OR of all the endpoint CTR flags) cannot be cleared directly, only by clearing the CTR flags in the Endpoint registers.

Bit 7 = CTR Correct Transfer.

This bit is set by hardware when a correct transfer operation is performed. This bit is an OR of all CTR flags (CTR0 in the EP0R register and CTR_RX and CTR_TX in the EPnRXR and EPnTXR registers). By looking in the USBSR register, the type of transfer can be determined from the PID[1:0] bits for Endpoint 0. For the other Endpoints, the Endpoint of the interest was made is identified by the EP[1:0] bits and the type of transfer by the IN/OUT bit.

0: No Correct Transfer detected

1: Correct Transfer detected

Note: A transfer where the device sent a NAK or STALL handshake is considered not correct (the host only sends ACK handshakes). A transfer is considered correct if there are no errors in the PID and CRC fields, if the DATA0/DATA1 PID is sent as expected, if there were no data overruns, bit stuffing or framing errors.

Bit 6 = Reserved, forced by hardware to 0.

Bit 5 =**SOVR** Setup Overrun.

This bit is set by hardware when a correct Setup transfer operation is performed while the software is servicing an interrupt which occured on the same Endpoint (CTR0 bit in the EP0R register is still set when SETUP correct transfer occurs).

0: No SETUP overrun detected

1: SETUP overrun detected

When this event occurs, the USBSR register is not updated because the only source of the SOVR

event is the SETUP token reception on the Control Endpoint (EP0).

Bit 4 = ERR Error.

This bit is set by hardware whenever one of the errors listed below has occurred:

0: No error detected

1: Timeout, CRC, bit stuffing, nonstandard framing or buffer overrun error detected

Note: Refer to the ERR[2:0] bits in the USBSR register to determine the error type.

Bit 3 = **SUSP** Suspend mode request.

This bit is set by hardware when a constant idle state is present on the bus line for more than 3 ms, indicating a suspend mode request from the USB.

The suspend request check is active immediately after each USB reset event and is disabled by hardware when suspend mode is forced (FSUSP bit in the USBCTLR register) until the end of resume sequence.

Bit 2 = **ESUSP** End Suspend mode.

This bit is set by hardware when, during suspend mode, activity is detected that wakes the USB interface up from suspend mode.

This interrupt is serviced by a specific vector, in order to wake up the ST7 from HALT mode.

0: No End Suspend detected

1: End Suspend detected

Bit 1 = **RESET** *USB* reset.

This bit is set by hardware when the USB reset sequence is detected on the bus.

0: No USB reset signal detected

1: USB reset signal detected

Note: The DADDR, EP0R, EP1RXR, EP1TXR, EP2RXR and EP2TXR registers are reset by a USB reset.

Bit 0 = **SOF** Start of frame.

This bit is set by hardware when a SOF token is received on the USB.

0: No SOF received

1: SOF received

Note: To avoid spurious clearing of some bits, it is recommended to clear them using a load instruction where all bits which must not be altered are set, and all bits to be cleared are reset. Avoid readmodify-write instructions like AND, XOR...

INTERRUPT MASK REGISTER (USBIMR)

Read/Write

Reset Value: 0000 0000 (00h)

7 0

CTRM 0 SOVR RERRM SUSP ESUSP RESET M SOFM

These bits are mask bits for all the interrupt condition bits included in the USBISTR register. Whenever one of the USBIMR bits is set, if the corresponding USBISTR bit is set, and the I- bit in the CC register is cleared, an interrupt request is generated. For an explanation of each bit, please refer to the description of the USBISTR register.

CONTROL REGISTER (USBCTLR)

Read/Write

Reset value: 0000 0110 (06h)

Bit 7 = **RSM** Resume Detected

This bit shows when a resume sequence has started on the USB port, requesting the USB interface to wake-up from suspend state. It can be used to determine the cause of an ESUSP event.

0: No resume sequence detected on USB

1: Resume sequence detected on USB

Bit 6 = USB_RST USB Reset detected.

This bit shows that a reset sequence has started on the USB. It can be used to determine the cause of an ESUSP event (Reset sequence).

0: No reset sequence detected on USB

1: Reset sequence detected on USB

Bits [5:4] = Reserved, forced by hardware to 0.

Bit 3 = **RESUME** Resume.

This bit is set by software to wake-up the Host when the ST7 is in suspend mode.

0: Resume signal not forced

1: Resume signal forced on the USB bus.

Software should clear this bit after the appropriate delay.

Bit 2 = **PDWN** *Power down*.

This bit is set by software to turn off the 3.3V onchip voltage regulator that supplies the external pull-up resistor and the transceiver.

0: Voltage regulator on

1: Voltage regulator off

Note: After turning on the voltage regulator, software should allow at least 3 µs for stabilisation of the power supply before using the USB interface.

Bit 1 = **FSUSP** Force suspend mode.

This bit is set by software to enter Suspend mode. The ST7 should also be put in Halt mode to reduce power consumption.

0. Suspend mode inactive

1; Suspend mode active

When the hardware detects USB activity, it resets this bit (it can also be reset by software).

Bit 0 = **FRES** Force reset.

This bit is set by software to force a reset of the USB interface, just as if a RESET sequence came from the USB.

0: Reset not forced

1: USB interface reset forced.

The USB is held in RESET state until software clears this bit, at which point a "USB-RESET" interrupt will be generated if enabled.

DEVICE ADDRESS REGISTER (DADDR)

Read/Write

Reset Value: 0000 0000 (00h)

7 0 0 ADD6 ADD5 ADD4 ADD3 ADD2 ADD1 ADD0

Bit 7 = Reserved, forced by hardware to 0.

Bits 6:0 = ADD[6:0] Device address, 7 bits.

Software must write into this register the address sent by the host during enumeration.

Note: This register is also reset when a USB reset is received or forced through bit FRES in the US-BCTLR register.

USB STATUS REGISTER (USBSR)

Read only

Reset Value: 0000 0000 (00h)

7 0 PID1 PID0 IN 00 0 EF EP1 EP0

Bits 7:6 = **PID[1:0]** Token PID bits 1 & 0 for Endpoint 0 Control.

USB token PIDs are encoded in four bits. PID[1:0] correspond to the most significant bits of the PID field of the last token PID received by Endpoint 0. **Note:** The least significant PID bits have a fixed value of 01.

When a CTR interrupt occurs on Endpoint 0 (see register USBISTR) the software should read the PID[1:0] bits to retrieve the PID name of the token received.

The USB specification defines PID bits as:

PID1	PID0	PID Name
0	0	OUT
1	0	IN
1	1	SETUP

Bit 5 = IN/OUT Last transaction direction for Endpoint 1, 2, 3, 4 or 5.

This bit is set by hardware when a CTR interrupt occurs on Endpoint 1, 2, 3, 4 or 5.

0: OUT transaction
1: IN transaction

Bits 4:3 = Reserved, forced by hardware to 0.

Bits $2:0 = \mathbf{EP[2:0]}$ Endpoint number.

These bits identify the endpoint which required attention.

000 = Endpoint 0

001 = Endpoint 1

010 = Endpoint 2

011 = Endpoint 3

100 = Endpoint 4

101 = Endpoint 5

ERROR STATUS REGISTER (ERRSR)

Read only

Reset Value: 0000 0000 (00h)

7							0
0	0	0	0	0	ERR2	ERR1	ERR0

Bits 7:3 =Reserved, forced by hardware to 0.

These bits identify the type of error which occurred.

ERR2	ERR1	ERR0	Meaning
0	0	0	No error
0	0	1	Bitstuffing error
0	1	0	CRC error
0	1	1	EOP error (unexpected end of packet or SE0 not followed by J-state)
1	0	0	PID error (PID encoding error, unexpected or unknown PID)
1	0	1	Memory over / underrun (mem- ory controller has not an- swered in time to a memory data request)
1	1	1	Other error (wrong packet, timeout error)

Note: these bits are set by hardware when an error interrupt occurs and are reset automatically when the error bit (USBISTR bit 4) is cleared by software.

USB INTERFACE (Cont'd) ENDPOINT 0 REGISTER (EP0R)

Read/Write

Reset value: 0000 0000(00h)

7 0

CTR0	DTOG _TX	STAT_ TX1	STAT_ TX0	0		STAT_ RX1	
------	-------------	--------------	--------------	---	--	--------------	--

This register is used for controlling Endpoint 0. Bits 6:4 and bits 2:0 are also reset by a USB reset, either received from the USB or forced through the FRES bit in USBCTLR.

Bit 7 = CTR0 Correct Transfer.

This bit is set by hardware when a correct transfer operation is performed on Endpoint 0. This bit must be cleared after the corresponding interrupt has been serviced.

0: No CTR on Endpoint 0

1: Correct transfer on Endpoint 0

Bit 6 = **DTOG_TX** Data Toggle, for transmission transfers.

It contains the required value of the toggle bit (0=DATA0, 1=DATA1) for the next transmitted data packet. This bit is set by hardware or reception of a SETUP PD INTOG_TK budles only when the transmitter has received the ACK signal from the USB host. DTOG_TX and also DTOG_RX are normally updated by hardware, on receipt of a relevant PID. They can be also written by the user, both for testing purposes and to force a specific (DATA0 or DATA1) token.

Bits 5:4 = **STAT_TX** [1:0] Status bits, for transmission transfers.

These bits contain the information about the endpoint status, which are listed below

Table 16. Transmission Status Encoding

STAT_TX1	STAT_TX0	Meaning
0	0	DISABLED: no function can be executed on this endpoint and messages related to this endpoint are ignored.
0	1	STALL : the endpoint is stalled and all transmission requests result in a STALL handshake.
1	0	NAK : the endpoint is NAKed and all transmission requests result in a NAK handshake.
1	1	VALID: this endpoint is enabled (if an address match occurs, the USB interface handles the transaction).

These bits are written by software. Hardware sets the STAT_TX and STAT_RX bits to NAK when a correct transfer has occurred (CTR=1) addressed to this endpoint; this allows software to prepare the next set of data to be transmitted.

Bit 2 = **DTOG_RX** Data Toggle, for reception transfers.

It contains the expected value of the toggle bit (0=DATA0, 1=DATA1) for the next data packet. This bit is cleared by hardware in the first stage (Setup Stage) of a control transfer (SETUP transactions start always with DATA0 PID). The receiver toggles DTOG_RX only if it receives a correct data packet and the packet's data PID matches the receiver sequence bit.

Bits 1:0 = **STAT_RX** [1:0] Status bits, for reception transfers.

These bits contain the information about the endpoint status, which are listed below:

Table 17. Reception Status Encoding

STAT_RX1	STAT_RX0	Meaning
0	0	DISABLED: no function can be executed on this endpoint and messages related to this endpoint are ignored.
0	1	STALL: the endpoint is stalled and all reception requests result in a STALL handshake.
1	0	NAK : the endpoint is NAKed and all reception requests result in a NAK handshake.
1	1	VALID: this endpoint is ena- bled (if an address match oc- curs, the USB interface handles the transaction).

These bits are written by software. Hardware sets the STAT_RX and STAT_TX bits to NAK when a correct transfer has occurred (CTR=1) addressed to this endpoint, so the software has the time to examine the received data before action vielding a new transaction.

Note 1:

If a SETUP transaction is received while the status is different from DISABLED, it is acknowleded and the two directional status bits are set to NAK by hardware.

Note 2:

When a STALL is answered by the USB device, the two directional status bits are set to STALL by hardware.

ENDPOINT TRANSMISSION REGISTER (EP1TXR, EP2TXR, EP3TXR, EP4TXR, EP5TXR)

Read/Write

Reset value: 0000 0000 (00h)

7							0
0	0	0	0	CTR_T X	DTOG _TX	STAT_ TX1	STAT_ TX0

This register is used for controlling Endpoint 1, 2, 3, 4 or 5 transmission. Bits 2:0 are also reset by a

USB reset, either received from the USB or forced through the FRES bit in the USBCTLR register.

Bits [7:4] = Reserved, forced by hardware to 0.

Bit 3 = CTR TX Correct Transmission Transfer.

This bit is set by hardware when a correct transfer operation is performed in transmission. This bit must be cleared after the corresponding interrupt has been serviced.

- 0: No CTR in transmission on Endpoint 1, 2, 3, 4 or 5
- 1: Correct transfer in transmission on Endpoint 1, 2, 3, 4 or 5

Bit 2 = **DTOG_TX** Data Toggle, for transmission transfers.

This bit contains the required value of the toggle bit (0=DATA0, 1=DATA1) for the next data packet. DTOG_TX toggles only when the transmitter has received the ACK signal from the USB host. DTOG_TX and DTOG_RX are normally updated by hardware, at the receipt of a relevant PID. They can be also written by the user, both for testing purposes and to force a specific (DATA0 or DATA1) token.

Bits [1:1] • STAT [1:0] Status bits, for transmission transfers.

These bits contain the information about the endpoint status, which is listed below

Table 18. Transmission Status Encoding

STAT_TX1	STAT_TX0	Meaning			
0	0	DISABLED: transmission transfers cannot be executed.			
0	0 1 STALL: the endpoint is s and all transmission requ result in a STALL hands				
1	0	NAK : the endpoint is naked and all transmission requests result in a NAK handshake.			
1	1	VALID : this endpoint is enabled for transmission.			

These bits are written by software, but hardware sets the STAT_TX bits to NAK when a correct transfer has occurred (CTR=1) addressed to this endpoint. This allows software to prepare the next set of data to be transmitted.

ENDPOINT 2 RECEPTION REGISTER (EP2RXR)

Read/Write

Reset value: 0000 0000 (00h)

7	7							0
(0	0	0	0	CTR_R X	DTOG _RX	STAT_ RX1	STAT_ RX0

This register is used for controlling Endpoint 2 reception. Bits 2:0 are also reset by a USB reset, either received from the USB or forced through the FRES bit in the USBCTLR register.

Bits [7:4] = Reserved, forced by hardware to 0.

Bit 3 = CTR_RX Reception Correct Transfer. This bit is set by hardware when a correct transfer operation is performed in reception. This bit must be cleared after that the corresponding interrupt has been serviced.

Bit 2 = DTOG_RX Data Toggle for reception transfers.

It contains the expected Mue of the toggle bit (0=DATA0, 1=DATA1) for the next data packet.

The receiver toggles DTOG_RX only if it receives acorrect data packet and the packet's data PID matches the receiver sequence bit.

Bits [1:0] = **STAT_RX** [1:0] Status bits, for reception transfers.

These bits contain the information about the endpoint status, which is listed below:

Table 19. Reception Status Encoding

STAT_RX1	STAT_RX0	Meaning
0	0	DISABLED: reception transfers cannot be executed.
0	1	STALL: the endpoint is stalled and all reception requests result in a STALL handshake.
1	0	NAK : the endpoint is naked and all reception requests result in a NAK handshake.
1	1	VALID : this endpoint is enabled for reception.

These bits are written by software, but hardware sets the STAT_BX bits to NAT when a correct transfer has occurred (CTn-1) addressed to this chdpoint, so the software has the time to examine the received data before acknowledging a new transaction.

RECEPTION COUNTER REGISTER (CNT0RXR)

Read/Write

Reset Value: 0000 0000 (00h)

7							0
0	0	0	0	CNT3	CNT2	CNT1	CNT0

This register contains the allocated buffer size for endpoint 0 reception, setting the maximum number of bytes the related endpoint can receive with the next OUT or SETUP transaction. At the end of a reception, the value of this register is the max size decremented by the number of bytes received (to determine the number of bytes received, the software must subtract the content of this register from the allocated buffer size).

TRANSMISSION COUNTER REGISTER (CNT0TXR, CNT1TXR, CNT3TXR, CNT4TXR, CNT5TXR)

Read/Write

Reset Value 0000 0000 (00h)

This register contains the number of bytes to be transmitted by Endpoint 0, 1, 3, 4 or 5 at the next IN token addressed to it.

RECEPTION COUNTER REGISTER (CNT2RXR)

Read/Write

Reset Value: 0000 0000 (00h)

This register contains the allocated buffer size for endpoint 2 reception, setting the maximum number of bytes the related endpoint can receive with the next OUT transaction. At the end of a reception, the value of this register is the max size decremented by the number of bytes received (to determine the number of bytes received, the software must subtract the content of this register from the allocated buffer size).

TRANSMISSION COUNTER REGISTER (CNT2TXR)

Read/Write

Reset Value 0000 0000 (00h)

This register contains the number of bytes to be transmitted by Endpoint 2 at the next IN token addressed to it.

12.4 SMARTCARD INTERFACE (CRD)

12.4.1 Introduction

The Smartcard Interface (CRD) provides all the required signals for acting as a smartcard interface device.

The interface is electrically compatible with (and certifiable to) the ISO7816, EMV, GSM and WHQL standards.

Both synchronous (e.g. memory cards) and asynchronous smartcards (e.g. microprocessor cards) are supported.

The CRD generates the required voltages to be applied to the smartcard lines.

The power-off sequence is managed by the CRD.

Card insertion or card removal is detected by the CRD using a card presence switch connected to the external CRDDET pin. If a card is removed, the CRD automatically deactivates the smartcard using the ISO7816 deactivation sequence.

An maskable interrupt is generated when a card is inserted or removed.

Any malfunction is reported to the microcontroller via the Smartcard Interrupt Pending Register

(CRDIPR) and Smartcard Status (CRDSR) Registers.

12.4.2 Main features

- Support for ISO 7816-3 standard
- Character mode
- 1 transmit buffer and 1 receive buffer
- 4-Mhz fixed card clock
- 11-bit etu (elementary time unit) counter
- 9-bit guardtime counter
- 24-bit general purpose waiting time counter
- Parity generation and checking
- Automatic character repetition on parity error detection in transmission mode
- Automatic retry on parity error detection in reception mode
- Card power-off deactivation sequence generation
- Manual mode for driving the card I/O directly for synchronous protocols

12.4.3 Functional Description

Figure 31 gives an overview of the smartcard interface.

12.4.3.1 Power Supply Management

Smartcard Power Supply Selection

The Smartcard interface consists of a power supply output on the CRDVCC pin and a set of card interface I/Os which are powered by the same rail.

The card voltage (CRDVCC) is user programmable via the VCARD [1:0] bits in the CRDCR register (refer to the Smartcard Interface section).

Four voltage values can be selected: 5V, 3 V, 1.8 V or 0V.

Current Overload Detection and Card Removal

For each voltage, when an overload current is detected (refer to section 12.4 on page 57), or when a card is removed, the CRDVCC power supply output is directly connected to ground.

12.4.3.2 I/O Driving Modes

Smartcard I/Os are driven in two principal modes:

- UART mode (i.e. when the UART bit of the CRDCR register is set)
- Manual mode, driven directly by software using the Smartcard Contact register (i.e. when the UART bit of the CRDCR register is reset).

Card power-on activation must driven by software.

Card deactivation is hardled autor adically by the Power-off functional state in achine bardware

12.4.3.3 UART Mode

Two registers are connected to the UART shift register: CRDTXB for transmission and CRDRXB for reception. They act as buffers to off-load the CPU.

A parity checker and generator is coupled to the shifter.

Character repetition and retry are supported.

The UART is in reception mode by default and switches automatically to transmission mode when a byte is written in the buffer.

Priority is given to transmission.

Elementary Time Unit Counter

This 11-bit counter controls the working frequency of the UART. The operating frequency of the clock is the same as the card clock frequency (i.e. 4 MHz).

A compensation mode can be activated via the COMP bit of the CRDETU1 register to allow a frequency granularity down to a half-etu.

Note: The decimal value is limited to a half clock cycle. The bit duration is not fixed. It alternates between n clock cycles and n-1 clock cycles, where n is the value to be written in the CRDETU register. The character duration (10 bits) is also equal to $10^*(n - \frac{1}{2})$ clock cycles This is precise enough to obtain the character duration specified by the ISO7816-3 standard.

For example, if F=372 and D=32 (F being the clock rate conversion factor and D the baud rate adjustment), then etu =11.625 clock cycles.

To achieve this clock rate, compensation mode must be activated and the etu duration must be programmed to 12 clock cycles.

The result will be an average character duration of 11.5 clock cycles (for 10 bits).

See Figure 32.

Guardtime country / C T

The guarding bounter is 9 bit counter which manages the character frame. It controls the duration between two consecutive characters in transmission.

It is incremented at the etu rate.

No guardtime is inserted for the first character transmitted.

The guardtime between the last byte received from the card and the next byte transmitted by the reader must be handled by software.

Figure 32. Compensation Mode

www.BDTIC.com/ST

Waiting Time Counter

The Waiting Time counter is a 24-bit counter used to generate a timeout signal.

The elementary time unit counter acts as a prescaler to the Waiting Time counter which is incremented at the etu rate.

The Waiting Time Counter can be used in both UART mode and Manual mode and acts in different ways depending on the selected mode.

The CRDWT2, CRDWT1 and CRDWT0 are load registers only, the counter itself is not directly accessible.

UART Mode

The load conditions are either:

 A Start bit is detected while UART bit =1 and the WTEN bit =1.

or

A write access to the CRDWT2 register is performed while the UART bit = 1 and the WTEN bit = 0. In this case, the Waiting Time counter can be used as a general purpose timer.

In UART mode, if the WTEN bit of the CRDCR register is set, the counter is loaded automatically on start bit detection. Software can change the time out value on-the fly by writing to the CRDWT registers. For example, in the case of tware must load the Block Waiting Time (BWT) time-out in the CRDWT registers before the start

bit of the last transmitted character.

Then, after transmission of this last character, signalled by the TXC interrupt, software must write the CWT value (Character Waiting Time) in the CRDWT registers. See example in Figure 33.

Manual mode

The load conditions are:

A write access to the CRDWT2 register is performed while the UART bit = 0 and the WTEN bit
 = 0

In Manual mode, if the WTEN bit of the CRDCR register is reset, the timer acts as a general purpose timer. The timer is loaded when a write access to the CRDWT2 register occurs. The timer starts when the WTEN bit = 1.

12.4.3.4 Interrupt generator

The Smartcard Interface has 2 interrupt vectors:

- Card Insertion/Removal Interrupt
- CRD Interrupt

The CRD interrupt is cleared when software reads the CRDIPR register. The Card Insertion/Removal is an external interrupt and is cleared automatically by hardware at the end of the interrupt service outine (IRET instruction).

If an interrult coairs while the CRDIPR register is being read, the corresponding bit will be set by hardware after the read access is done.

Figure 33. Waiting Time Counter Example

12.4.3.5 Card detection mechanism

The CRDDET bit in the CRDCR Register indicates if the card presence detector (card switch) is open or closed when a card is inserted. When the CRDIRF bit of the CRDSR is set, it indicates that a card is present.

To be able to power-on the smartcard, card presence is mandatory. Removing the smartcard will automatically start the ISO7816-3 card deactivation sequence (see Section 12.4.3.6).

There is no hardware debouncing: The CRDIRF bit changes whenever the level on the CRDDET pin changes. The card switch can generate an interrupt which can be used to wake up the device from suspend mode and for software debouncing.

Three different cases can occur:

 The microcontroller is in run mode, waiting for card insertion:

Card insertion generates an interrupt and the

CRDIRF bit in the CRDSR register is set. Debouncing is managed by software. After the time required for debouncing, if the CRDIRF bit is set, the CRDVCC bit in the CRDCR register is set by software to apply the selected voltage to the CRDVCC pin

 The microcontroller is in suspend mode and a card is inserted:

The ST7 is woken up by the interrupt. The card insertion is then handled in the same way as in the previous case.

- The card is removed:
 - The CRDIRF bit is reset without hardware debouncing
 - A Card Insertion/Removal interrupt is generated, (if enabled by the CRDIRM bit in the MISCR2 register)
 - The CRDVCC bit is immediately reset by hardware, starting the card deactivation sequence.

Figure 34. Card detection block diagram

12.4.3.6 Card Deactivation Sequence

This sequence can be activated in two different ways:

- Automatically as soon as the card presence detector detects a card removal (via the CRDIRF bit in the CRDSR register, refer to Section 12.4.3.5).
- By software, writing the CRDVCC bit in the CRD-CR register, for example:
 - If there is a smartcard current overflow (i.e. when the IOVFF bit in the CRDSR register is set)
 - If the voltage is not within the specified range (i.e. when the VCARDOK bit in the CRDSR register is cleared), but software must clear the CRDVCC bit in the CRDCCR register to start the deactivation sequence.

When the CRDVCC bit is cleared, this starts the deactivation sequence. CRDCLK, CRDIO, CRDC4 and CRDC8 pins are then deactivated as shown in Figure 35:

Figure 35. Card deactivation sequence

Figure 36. Card voltage selection and power OFF block diagram

Figure 37. Power Off Timing Diagram

Note: Refer to the Electrical Characteristics section for the values of $t_{\mbox{\scriptsize ON}}$ and $t_{\mbox{\scriptsize OFF}}.$

12.4.4 Register Description

SMARTCARD INTERFACE CONTROL REGISTER (CRDCR)

Read/Write

Reset Value: 0000 0000 (00h)

7 0

		VCAR D 1					
--	--	-------------	--	--	--	--	--

Bit 7 = CRDRST Smartcard Interface Reset.

This bit is set by software to reset the UART of the Smartcard interface.

0: No Smartcard UART Reset

1: Smartcard UART Reset

Bit 6 = **CRDDET** Card Presence Detector.

This bit is set and cleared by software to configure the card presence detector switch.

0: Switch open if no card is present

1: Switch closed if no card is present

Bits [5:4] = **VCARDI1:0]** Card voltage selection. These bits select the sard voltage.

Bit 1	Bit 0	Vcard
0	0	0V
0	1	1.8V
1	0	3V
1	1	5V

Bit 3 = **UART** *UART Mode Selection*.

This bit is set and cleared by software to select UART or manual mode.

- 0: CRDIO pin is a copy of the CRDIO bit in the CRDCCR register (Manual mode).
- 1: CRDIO pin is the output of the smartcard UART (UART mode).

Caution: Before switching from Manual mode to UART mode, software must set the CRDIO bit in the CRDCCR register.

Bit 2 = WTEN Waiting Time Counter enable.

- 0: Waiting Time counter stopped. While WTEN = 0, a write access to the CRDWT2 register loads the Waiting time counter with the load value held in the CRDWT0, CRDWT1 and CRDWT2 registers
- 1: Start counter. In UART mode, the counter is automatically reloaded on start bit detection.

Bit 1 = **CREP** Automatic character repetition in case of parity error.

- 0: In reception mode: no parity error signal indication (no retry on parity error). In transmission mode: no error signal processing. No retransmission of a refused character on parity error.
- 1: Automatic parity management: In transmission mode: up to 4 character repetitions on parity error.

In reception mode: up to 4 retries are made on parity error.

The PARF parity error flag is set by hardware if a parity error is detected.

If the transmitted character is refused, the PARF bit is set (but the TXCF bit is reset) and an interrupt generated if the PARM on is jet.

Note: I CREP=1, the PART flag is set at the 5th error (after 4 enaracter repetitions or 4 retries).

If CREP=0, the PARF bit is set after the first parity error.

Bit 0 = **CONV** ISO convention selection.

- 0: Direct convention, the B0 bit (LSB) is sent first, a '1' is a level 1 on the Card I/O pin, the parity bit is added after the B7 bit.
- 1: Inverse convention, the B7 bit (MSB) is sent first, a '1' is a level 0 on Card I/O pin, the parity bit is added after the B0 bit.

Note: To detect the convention used by any card, apply the following rule. If a card uses the convention selected by the reader, an RXC event occurs at answer to reset. Otherwise a parity error also occurs.

SMARTCARD INTERFACE STATUS REGISTER (CRDSR)

Read only (Read/Write on some bits) Reset Value: 1000 0000 (80h)

7

TXBE CRD IOVE	VCARD OK	WTF	TXC F	RXC F	PAR F

0: Transmit buffer is not empty

1: Transmit buffer is empty

Bit 6 = CRDIRF Card Insertion/Removal Flag.

- Read only

0: No card is present

1: A card is present

Bit 5 = **IOVF** Card Overload Current Flag.

- Read only

0: No card overload current

1: Card overload current

BDT

Bit 4 = VCARDOK Card voltage status Flag.

- Read only

0: The card voltage is not in the specified range

1: The card voltage is within the specified range

Bit 3 = WTF Waiting Time Counter overflow Flag.

- Read only

0

0: The WT Counter has not reached its maximum value

1: The WT Counter has reached its maximum value

Bit 2 = **TXCF** Transmitted character Flag.

- Read/Write

This bit is set by hardware and cleared by software.

0: No character transmitted

1: A character has been transmitted

Bit 1 = RXCF Received character Flag.

- Read only

This bit is set by hardware and cleared by hardware when the CRDRXB buffer is read.

0: No character received

1: A character has been received

Bit 0 = **PARF** Parity Error Flag.

- Read/Write

This bit is set by hardware and cleared by soft-

0: No pany enom / S T 1/ Parity error

Note: When a character is received, the RXCF bit is always set. When a character is received with a parity error, the PARF bit is also set.

SMARTCARD CONTACT CONTROL REGISTER (CRDCCR)

Read/Write

Reset Value: 00xx xx00 (xxh)

7 0
CLK - CRD CRD CRD CRD CRD CRD

CLK - CRD	CLK SEL	-						
---	------------	---	--	--	--	--	--	--

Note: To modify the content of this register, the LD instruction must be used (do not use the BSET and BRES instructions).

Bit 7 = **CLKSEL** Card clock selection.

This bit is set and cleared by software.

- The signal on the CRDCLK pin is a copy of the CRDCLK bit.
- The signal on the CRDCLK pin is a 4MHz frequency clock.

Note: To start the clock at a known level, the CRD-CLK bit should be changed before the CLKSEL bit.

Bit 6 = Reserved, must be kept cleared

Bit 5 = CRDC8 CRDC8 pin control.

Reading this bit returns the value present on the CRDC8 pin. Writing this bit outputs the bit value on the pin.

Bit 4 = **CRDC4** CRDC4 pin control

Reading this bit returns the value present on the CRDC4 pin. Writing this bit outputs the bit value on the pin.

Bit 3 = **CRDIO** CRDIO pin control.

This bit is active only if the UART bit in the CRDCR Register is reset. Reading this bit returns the value present on the CRDIO pin.

If the UART bit is reset:

- Writing "0" forces a low level on the CRDIO pin
- Writing "1" forces the CRDIO pin to open drain Hi-Z.

Bit 2 = CRDCLK CRDCLK pin control

This bit is active only if the CLKSEL bit of the CRD-CCR register is reset. Reading this bit returns the value present in the register (not the CRDCLK pin value).

When the CLKSEL bit is reset:

- 0: Level 0 to be applied on CRDCLK pin.
- 1: Level 1 to be applied on CRDCLK pin.

Note: To ensure that the clock stops at a given value, write the desired value in the CRDCLK bit prior to changing the CLKSEL bit from 1 to 0.

t 1 = CRDRST CRDPS pirtol.

Reading this bit returns the value present on the RLRST pin. Writing this sit outputs the bit value on the pin.

Bit 0 = **CRDVCC** CRDVCC Pin Control.

This bit is set and cleared by software and forced to 0 by hardware when no card is present (CRDIRF bit=0).

- 0: No voltage to be applied on the CRDVCC pin.
- 1: The selected voltage must be applied on the CRDVCC pin.

CRDWT0

Read/Write

Reset Value: 1000 0000 (80h)

7 0 WT 7 WT6 WT5 WT4 WT3 WT2 WT1 WT0

WT: Character waiting time value expressed in ETU (0 / 16777215).

The CRDWT0, CRDWT1 and CRDWT2 registers hold the load value of the Waiting Time counter.

Note: A read operation does not return the counter value.

This counter can be used as a general purpose timer.

If the WTEN bit of the CRDCR register is reset, the counter is reloaded when a write access in the CRDWT2 register occurs. It starts when the WTEN bit is set.

If the WTEN bit in the CRDCR register is set and if UART mode is activated, the counter acts as an autoreload timer. The timer is reloaded when a start bit is sent of Getected. An it terrupt is generated if the timer werflows between two consecutive start bits.

Note: When loaded with a 0 value, the Waiting Time counter stays at 0 and the WTF bit = 1.

13 INSTRUCTION SET

13.1 CPU ADDRESSING MODES

The CPU features 17 different addressing modes which can be classified in 7 main groups:

Addressing Mode	Example			
Inherent	nop			
Immediate	ld A,#\$55			
Direct	ld A,\$55			
Indexed	ld A,(\$55,X)			
Indirect	ld A,([\$55],X)			
Relative	jrne loop			
Bit operation	bset byte,#5			

The CPU Instruction set is designed to minimize the number of bytes required per instruction: To do

so, most of the addressing modes may be subdivided in two sub-modes called long and short:

- Long addressing mode is more powerful because it can use the full 64 Kbyte address space, however it uses more bytes and more CPU cycles
- Short addressing mode is less powerful because it can generally only access page zero (0000h -00FFh range), but the instruction size is more compact, and faster. All memory to memory instructions use short addressing modes only (CLR, CPL, NEG, BSET, BRES, BTJT, BTJF, INC, DEC, RLC, RRC, SLL, SRL, SRA, SWAP)

The ST7 Assembler optimizes the use of long and short addressing modes.

Table 22. CPU Addressing Mode Overview

Mode			Syntax	Destination	Pointer Address (Hex.)	Pointer Size (Hex.)	Length (Bytes)	
Inherent			nop				+ 0	
Immediate	\ A /\ /	1/\ A /	I A # \$50		Om	CT	+ 1	
Short	Di ve vit V	V VV .	1 A \$ 10	00. . F ■			+ 1	
Long	Direct		ld A,\$1000	0000FFFF			+ 2	
No Offset	Direct	Indexed	ld A,(X)	00FF			+ 0	
Short	Direct	Indexed	ld A,(\$10,X)	001FE			+ 1	
Long	Direct	Indexed	ld A,(\$1000,X)	0000FFFF			+ 2	
Short	Indirect		ld A,[\$10]	00FF	00FF	byte	+ 2	
Long	Indirect		ld A,[\$10.w]	0000FFFF	00FF	word	+ 2	
Short	Indirect	Indexed	ld A,([\$10],X)	001FE	00FF	byte	+ 2	
Long	Indirect	Indexed	ld A,([\$10.w],X)	0000FFFF	00FF	word	+ 2	
Relative	Direct		jrne loop	PC+/-127			+ 1	
Relative	Indirect		jrne [\$10]	PC+/-127	00FF	byte	+ 2	
Bit	Direct		bset \$10,#7	00FF			+ 1	
Bit	Indirect		bset [\$10],#7	00FF	00FF	byte	+ 2	
Bit	Direct	Relative	btjt \$10,#7,skip	00FF			+ 2	
Bit	Indirect	Relative	btjt [\$10],#7,skip	00FF	00FF	byte	+ 3	

13.1.1 Inherent

All Inherent instructions consist of a single byte. The opcode fully specifies all the required information for the CPU to process the operation.

Inherent Instruction	Function
NOP	No operation
TRAP	S/W Interrupt
WFI	Wait For Interrupt (Low Power Mode)
HALT	Halt Oscillator (Lowest Power Mode)
RET	Sub-routine Return
IRET	Interrupt Sub-routine Return
SIM	Set Interrupt Mask (level 3)
RIM	Reset Interrupt Mask (level 0)
SCF	Set Carry Flag
RCF	Reset Carry Flag
RSP	Reset Stack Pointer
LD	Load
CLR	Clear
PUSH/POP	Push/Pop to/from the stack
INC/DEC	Increment/Discrenter t
TNZ	Fest Negative of Lerc
CPL, NEG	1 or 2 Complement
MUL	Byte Multiplication
SLL, SRL, SRA, RLC, RRC	Shift and Rotate Operations
SWAP	Swap Nibbles

13.1.2 Immediate

Immediate instructions have two bytes, the first byte contains the opcode, the second byte contains the operand value.

Immediate Instruction	Function
LD	Load
CP	Compare
ВСР	Bit Compare
AND, OR, XOR	Logical Operations
ADC, ADD, SUB, SBC	Arithmetic Operations

13.1.3 Direct

In Direct instructions, the operands are referenced by their memory address.

The direct addressing mode consists of two submodes:

Direct (short)

The address is a byte, thus requires only one byte after the opcode, but only allows 00 - FF addressing space.

Direct (long)

The address is a word, thus allowing 64 Kbyte addressing space, but requires 2 bytes after the opcode.

13.1.4 Indexed (No Offset, Short, Long)

In this mode, the operand is referenced by its memory address, which is defined by the unsigned addition of an index register (X or Y) with an offset.

The indirect addressing mode consists of three sub-modes:

Indexed (No Offset)

There is no offset, (no extra byte after the opcode), and allows 00 - FF addressing pace.

Indexe I (Slior!)

The offset is a byte, thus requires only one byte after the opcode and allows 00 - 1FE addressing space.

Indexed (long)

The offset is a word, thus allowing 64 Kbyte addressing space and requires 2 bytes after the opcode.

13.1.5 Indirect (Short, Long)

The required data byte to do the operation is found by its memory address, located in memory (pointer).

The pointer address follows the opcode. The indirect addressing mode consists of two sub-modes:

Indirect (short)

The pointer address is a byte, the pointer size is a byte, thus allowing 00 - FF addressing space, and requires 1 byte after the opcode.

Indirect (long)

The pointer address is a byte, the pointer size is a word, thus allowing 64 Kbyte addressing space, and requires 1 byte after the opcode.

13.1.6 Indirect Indexed (Short, Long)

This is a combination of indirect and short indexed addressing modes. The operand is referenced by its memory address, which is defined by the unsigned addition of an index register value (X or Y) with a pointer value located in memory. The pointer address follows the opcode.

The indirect indexed addressing mode consists of two sub-modes:

Indirect Indexed (Short)

The pointer address is a byte, the pointer size is a byte, thus allowing 00 - 1FE addressing space, and requires 1 byte after the opcode.

Indirect Indexed (Long)

The pointer address is a byte, the pointer size is a word, thus allowing 64 Kbyte addressing space, and requires 1 byte after the opcode.

Table 23. Instructions Supporting Direct, Indexed, Indirect and Indirect Indexed Addressing Modes

Long and Short Instructions	Function					
LD V	/Agan					
CP	Compare					
AND, OR, XOR	Logical Operations					
ADC, ADD, SUB, SBC	Arithmetic Additions/Substractions operations					
ВСР	Bit Compare					

Short Instructions Only	Function
CLR	Clear
INC, DEC	Increment/Decrement
TNZ	Test Negative or Zero
CPL, NEG	1 or 2 Complement
BSET, BRES	Bit Operations
BTJT, BTJF	Bit Test and Jump Operations
SLL, SRL, SRA, RLC, RRC	Shift and Rotate Operations
SWAP	Swap Nibbles
CALL, JP	Call or Jump subroutine

13.1.7 Relative mode (Direct, Indirect)

This addressing mode is used to modify the PC register value, by adding an 8-bit signed offset to it

Available Relative Direct/Indirect Instructions	Function
JRxx	Conditional Jump
CALLR	Call Relative

The relative addressing mode consists of two submodes:

Relative (Direct)

The offset is following the opcode.

Relative (Indirect)

The offset is defined in memory, which address follows the opcode.

IC.com/ST

13.2 INSTRUCTION GROUPS

The ST7 family devices use an Instruction Set consisting of 63 instructions. The instructions may

be subdivided into 13 main groups as illustrated in the following table:

Load and Transfer	LD	CLR						
Stack operation	PUSH	POP	RSP					
Increment/Decrement	INC	DEC						
Compare and Tests	СР	TNZ	BCP					
Logical operations	AND	OR	XOR	CPL	NEG			
Bit Operation	BSET	BRES						
Conditional Bit Test and Branch	BTJT	BTJF						
Arithmetic operations	ADC	ADD	SUB	SBC	MUL			
Shift and Rotates	SLL	SRL	SRA	RLC	RRC	SWAP	SLA	
Unconditional Jump or Call	JRA	JRT	JRF	JP	CALL	CALLR	NOP	RET
Conditional Branch	JRxx							
Interruption management	TRAP	WFI	HALT	IRET				
Condition Code Flag modification	SIM	RIM	SCF	RCF				

Using a pre-byte

The instructions are described with one to our opcodes.

In order to extend the number of available opcodes for an 8-bit CPU (256 opcodes), three different prebyte opcodes are defined. These prebytes modify the meaning of the instruction they precede.

The whole instruction becomes:

PC-2 End of previous instruction

PC-1 Prebyte PC opcode

PC+1 Additional word (0 to 2) according to the number of bytes required to compute the effective address

These prebytes anable instruct on in Y as well as indirect addressing modes to be implemented. They precede the opcode of the instruction in X or the instruction using direct addressing mode. The prebytes are:

PDY 90 Replace an X based instruction using immediate, direct, indexed, or inherent addressing mode by a Y one.

PIX 92 Replace an instruction using direct, direct bit, or direct relative addressing mode to an instruction using the corresponding indirect addressing mode.

It also changes an instruction using X indexed addressing mode to an instruction using indirect X indexed addressing mode.

PIY 91 Replace an instruction using X indirect indexed addressing mode by a Y one.

14 ELECTRICAL CHARACTERISTICS

14.1 ABSOLUTE MAXIMUM RATINGS

This product contains devices for protecting the inputs against damage due to high static voltages, however it is advisable to take normal precautions to avoid appying any voltage higher than the specified maximum rated voltages.

For proper operation it is recommended that V_I and V_O be higher than V_{SS} and lower than V_{DD} . Reliability is enhanced if unused inputs are connected to an appropriate logic voltage level (V_{DD} or V_{SS}).

Power Considerations. The average chip-junction temperature, T_{.I}, in Celsius can be obtained from:

TA + PD x RthJA Where: Ambient Temperature.

RthJA = Package thermal resistance

(junction-to ambient).

 $P_D = P_{INT} + P_{PORT}.$ $P_{INT} = I_{DD} \times V_{DD}$ (chip internal power). $P_{PORT} = P_{DD} \times P$

determined by the user)

Stresses above those listed as "absolute maximum ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these conditions is not implied. Exposure to maximum rating for extended periods may affect device reliability.

Symbol	Ratings	Value	Unit
V _{DD} - V _{SS}	Supply voltage	6.0	V
V _{IN}	Input voltage	V_{SS} - 0.3 to V_{DD} + 0.3	V
V _{OUT}	Output voltag e	V _{CS} 0.3 to V _{DD} + 0.3	V
ESD V	TST suscept pility	2000	V
ESDCard	ESD susceptibility for card pads	4000	V
I_{VDD_i}	Total current into V _{DD_i} (source)	250	mA
I _{VSS_i}	Total current out of V _{SS_i} (sink)	250	ША

General Warning: Direct connection to V_{DD} or V_{SS} of the I/O pins could damage the device in case of program counter corruption (due to unwanted change of the I/O configuration). To guarantee safe conditions, this connection has to be done through a typical $10K\Omega$ pull-up or pull-down resistor.

Thermal Characteristics

Symbol	Ratings		Value	Unit
R _{thJA}	Package thermal resistance	LQFP64 SO24 QFN24	60 80 42	°C/W
T _{Jmax}	Max. junction temperature		150	°C
T _{STG}	Storage temperature range		-65 to +150	°C
PD _{max}	Power dissipation	QFN24 SO24	600 500	mW

14.2 RECOMMENDED OPERATING CONDITIONS

GENERAL						
Symbol	Parameter	Conditions	Min	Тур	Max	Unit
V_{DD}	Supply voltage		4.0		5.5	V
fosc	External clock source			4		MHz
T _A	Ambient temperature range		0		70	°C

(Operating conditions $T_A = 0$ to $+70^{\circ}$ C unless otherwise specified)

CURRENT INJECTION ON I/O PORT AND CONTROL PINS									
Symbol	Parameter	Conditions	Min	Тур	Max	Unit			
I _{INJ+}	Total positive injected current ^(1,2)	V _{EXTERNAL} > V _{DD} (Standard I/Os) V _{EXTERNAL} > V _{CRDVCC} (Smartcard I/Os)			20	mA			
I _{INJ-}	Total negative injected current (3)	V _{EXTERNAL} < V _{SS} Digital pins Analog pins			20	mA			

Note 1: Positive injection

The I_{INJ+} is done through protection diodes insulated from the substrate of the die.

Note 2: For SmartCard I/Os, V_{CRDVCC} has to be considered.

Note 3: Negative injection

– The I_{INJ} is dor extravegory protection dodes NOT IN SULATED from the substrate of the die. The drawback is a small leakage (rew μA) induced inside the die when a negative injection is performed. This leakage is tolerated by the digital structure, but it acts on the analog line according to the impedance versus a leakage current of few μA (if the MCU has an AD converter). The effect depends on the pin which is submitted to the injection. Of course, external digital signals applied to the component must have a maximum impedance close to 50K Ω .

Location of the negative current injection:

 Pure digital pins can tolerate 1.6mA. In addition, the best choice is to inject the current as far as possible from the analog input pins.

General Note: When several inputs are submitted to a current injection, the maximum I_{INJ} is the sum of the positive (resp. negative) currents (instantaneous values).

RECOMMENDED OPERATING CONDITIONS (Cont'd)

 $(T_A=0 \text{ to } +70^{\circ}\text{C}, V_{DD}-V_{SS}=5.5\text{V} \text{ unless otherwise specified})$

Symbol	Parameter	Conditions	Min	Тур.	Max	Unit
	Supply current in RUN mode 1)	f _{OSC} = 4MHz		10	15	mA
	Supply current in WAIT mode 2)			3	9	mA
I _{DD}	Supply current in suspend mode	External I _{LOAD} = 0mA (USB transceiver enabled)			500	μΑ
	Supply current in HALT mode	External I _{LOAD} = 0mA (USB transceiver disabled)		50	100	μΑ

Notes:

- CPU running with memory access, all I/O pins in input mode with a static value at V_{DD} or V_{SS}; clock input (OSCIN)
 driven by external square wave.
- 2. All I/O pins in input mode with a static value at V_{DD} or V_{SS} ; clock input (OSCIN) driven by external square wave.
- T = 0... +70 °C, voltages are referred to V_{SS} unless otherwise specified:

O PORT	PINS						
Symbol	Parameter	Conditions	Min	Тур	Max	Unit	
V _{IL}	Input low level voltage	V _{DD} =5V			$0.3xV_{DD}$	V	
V _{IH}	Input high level voltage	V _{DD} =5V	$0.7xV_{DD}$	0.7xV _{DD}		V	
V _{HYS}	Schmidt trigger voltage hysteresis 1)			400		mV	
	Output low level voltage	I=-5mA			1.3		
V_{OL}	for Standard I/O port pins	I=-2mA			0.4	V	
V _{OH}	Output high level voltage	— J −3mA	V _{DD} -0.8	/			
ΙL	Input lackacie current	' _{SS} <v<sub>PIN<v<sub>D</v<sub></v<sub>	\cap m		1	μA	
R _{PU}	Pull-up equivalent rusistor	10.0	50	90	170	ΚΩ	
t _{OHL}	Output high to low level fall time for high sink I/O port pins (Port D) 2)		6	8	13		
t _{OHL}	Output high to low level fall time for standard I/O port pins (Port A, B or C) ²⁾	C _l =50pF	18		23	ns	
t _{OLH}	Output L-H rise time (Port D) 2)		7	9	14		
t _{OLH}	Output L-H rise time for standard I/O port pins (Port A, B or C) ²⁾		19		28		
t _{ITEXT}	External interrupt pulse time		1			t _{CPU}	

Note 1: Hysteresis voltage between Schmitt trigger switching levels. Based on characterization results, not tested.

Note 2: Guaranteed by design, not tested in production.

LED PINS						
Symbol	Parameter	Conditions	Min	Тур	Max	Unit
I _{Lsink}	Low current	Vpad > V _{DD} -2.4	2		4	
l	I _{Lsink} High current	Vpad > V _{DD} -2.4 for ROM device	5	6	8.4	mA
Lsink		Vpad > V _{DD} -2.4 for FLASH device	5	7	8.4	

14.3 SUPPLY AND RESET CHARACTERISTICS

 $(T = 0 \text{ to } +70^{\circ}\text{C}, V_{DD} - V_{SS} = 5.5\text{V} \text{ unless otherwise specified})$

	FAGE DETECTOR AND SUPERVISOR	· · ·		1	1	
Symbol	Parameter	Conditions	Min	Тур	Max	Unit
V _{IT+}	Reset release threshold (V _{DD} rising)			3.7	3.9	V
V _{IT-}	Reset generation threshold (V _{DD} falling)		3.3	3.5		V
V _{hys}	Hysteresis V _{IT+} - V _{IT-} 1)			200		mV
V _{tPOR}	V _{DD} rise time rate ¹⁾		20			ms/V

Note 1: Hysteresis voltage between Schmitt trigger switching levels. Based on characterization results, not tested.

14.4 CLOCK AND TIMING CHARACTERISTICS

14.4.1 General Timings

(Operating conditions $T_A = 0$ to $+70^{\circ}$ C unless otherwise specified)

Symbol	Parameter	Conditions	Min	Typ 1)	Max	Unit
t _{c(INST)}	Instruction cycle time		2	3	12	t _{CPU}
		f _{CPU} =4MHz	500	750	3000	ns
t _{v(IT)}	Interrupt reaction time ²⁾	_	10		22	t _{CPU}
		f _{pu=} Mhz	25	/ C	5.5	μS

^{*} Δt_{INST} is the number of t_{CPU} to finish the current instruction execution.

14.4.2 External Clock Source

Symbol	Parameter	Conditions	Min	Тур	Max	Unit
V _{OSCINH}	OSCIN input pin high level voltage		0.7xV _{DD}		V_{DD}	V
V _{OSCINL}	OSCIN input pin low level voltage		V _{SS}		$0.3xV_{DD}$	
$t_{w(OSCINH)}$ $t_{w(OSCINL)}$	OSCIN high or low time 3)	see Figure 40	15			ns
$t_{r(OSCIN)}$ $t_{f(OSCIN)}$	OSCIN rise or fall time 3)				15	113
ΙL	OSCx Input leakage current	$V_{SS} \leq V_{IN} \leq V_{DD}$			±1	μΑ

Notes:

- 1. Data based on typical application software.
- 2. Time measured between interrupt event and interrupt vector fetch. $\Delta t_{c(INST)}$ is the number of t_{CPU} cycles needed to finish the current instruction execution.
- 3. Data based on design simulation and/or technology characteristics, not tested in production.

CLOCK AND TIMING CHARACTERISTICS (Cont'd)

Figure 40. Typical Application with an External Clock Source

www.BDTIC.com/ST

CLOCK AND TIMING CHARACTERISTICS (Cont'd)

14.4.3 Crystal Resonator Oscillators

The ST7 internal clock is supplied with one Crystal resonator oscillator. All the information given in this paragraph are based on characterization results with specified typical external componants. In the application, the resonator and the load capaci-

tors have to be placed as close as possible to the oscillator pins in order to minimize output distortion and start-up stabilization time. Refer to the crystal resonator manufacturer for more details (frequency, package, accuracy...).

Symbol	Parameter	Conditio	ns	Min	Тур	Max	Unit
fosc	Oscillator Frequency 3)	MP: Medium power osc	illator		4		MHz
R _F	Feedback resistor			90		150	kΩ
C _{L1} C _{L2}	Recommanded load capacitances versus equivalent serial resistance of the crystal resonator (R _S)	See Table 5, "Recommended Values for 4 MHz Crystal Resonator," on page 21	(MP oscillator)	22		56	pF
i ₂	OSCOUT driving current	V_{DD} =5V V_{IN} = V_{SS}	(MP oscillator)	1.5		3.5	mA

Oscil.		Typical Crystal Resonator			C_{L1}	C_{L2}	t _{SU(osc)}	
Į O	SCII.	Reference		Reference Freq. Characteristic 1)		[pF]	[pF]	[ms] ²⁾
Crystal	MP	JAUCH	SS3-400-30-30/30	4MHz	Δf_{OSC} =[±30ppm _{25°C} ,±30ppm _{ΔTa}], Typ. R _S =60 Ω	33	33	7~10

Figure 41. Typical Application with a Crystal Resonator

Notes:

- 1. Resonator characteristics given by the crystal resonator manufacturer.
- 2. $t_{SU(OSC)}$ is the typical oscillator start-up time measured between V_{DD} =2.8V and the fetch of the first instruction (with a quick V_{DD} ramp-up from 0 to 5V (<50 μ s).
- 3. The oscillator selection can be optimized in terms of supply current using an high quality resonator with small R_S value. Refer to crystal resonator manufacturer for more details.

14.5 MEMORY CHARACTERISTICS

Subject to general operating conditions for V_{DD} , f_{OSC} , and T_A unless otherwise specified.

14.5.1 RAM and Hardware Registers

Symbol	Parameter	Conditions	Min	Тур	Max	Unit
V_{RM}	Data retention mode 1)	HALT mode (or RESET)	2			٧

Note 1: Minimum V_{DD} supply voltage without losing data stored in RAM (in HALT mode or under RESET) or in hardware registers (only in HALT mode). Not tested in production.

14.5.2 FLASH Memory

Operating Conditions: $f_{CPU} = 8 \text{ MHz}$.

DUAL VOL	TAGE FLASH MEMORY 1)					
Symbol	Parameter	Conditions	Min	Тур	Max	Unit
		Read mode			8	
f _{CPU}	Operating Frequency	Write / Erase mode, T _A =25°C				MHz

Note 1: Guaranteed by design.

Note 2: Data based on characterization results, not tested in production.

Note 3: V_{DD} = 4.75 V, Card consumption = 55mA, CRDCLK frequency = 4MHz, LED with a 3mA current, USB in reception mode and CPU in WFI mode.

www.BDTIC.com/ST

14.7 EMC CHARACTERISTICS

Susceptibility tests are performed on a sample basis during product characterization.

14.7.1 Functional EMS (Electro Magnetic Susceptibility)

Based on a simple running application on the product (toggling 2 LEDs through I/O ports), the product is stressed by two electro magnetic events until a failure occurs (indicated by the LEDs).

- ESD: Electro-Static Discharge (positive and negative) is applied on all pins of the device until a functional disturbance occurs. This test conforms with the IEC 1000-4-2 standard.
- FTB: A Burst of Fast Transient voltage (positive and negative) is applied to V_{DD} and V_{SS} through a 100pF capacitor, until a functional disturbance occurs. This test conforms with the IEC 1000-4-4 standard.

A device reset allows normal operations to be resumed. The test results are given in the table below based on the EMS levels and classes defined in application note AN1709.

14.7.1.1 Designing hardened software to avoid noise problems

EMC characterization and optimization are performed at component level with a typical applica-

tion environment and simplified MCU software. It should be noted that good EMC performance is highly dependent on the user application and the software in particular.

Therefore it is recommended that the user applies EMC software optimization and prequalification tests in relation with the EMC level requested for his application.

Software recommendations:

The software flowchart must include the management of runaway conditions such as:

- Corrupted program counter
- Unexpected reset
- Critical Data corruption (control registers...)

Prequalification trials:

Most of the common failures (unexpected reset and program counter corruption) can be reproduced by manually forcing a low state on the RE-SET pin or the Oscillator pins for 1 second.

To complete these trials, ESD stress can be applied directly on the device, over the range of specification values. When unexpected behaviour is detected, the software can be hardened to prevent unrecoverable errors occurring (see application note AN1015).

	\^\/\/\/\/		
Symbol	VV VV Parameter	Conditions	Level/ Class
V _{FESD}	Voltage limits to be applied on any I/O pin to induce a functional disturbance	V _{DD} =5V, T _A =+25°C, f _{OSC} =8MHz conforms to IEC 1000-4-2	2B
V _{FFTB}	Fast transient voltage burst limits to be applied through 100pF on V _{DD} and V _{DD} pins to induce a functional disturbance	V _{DD} =5V, T _A =+25°C, f _{OSC} =8MHz conforms to IEC 1000-4-4	4B

14.7.2 Electro Magnetic Interference (EMI)

Based on a simple application running on the product (toggling 2 LEDs through the I/O ports), the product is monitored in terms of emission. This emission test is in line with the norm SAE J 1752/3 which specifies the board and the loading of each pin.

Symbol	Parameter	Conditions	Monitored	Max vs. [f _{OSC} /f _{CPU}]		Unit
Symbol	i arameter	Conditions	Frequency Band	4/8MHz	4/4MHz	
			0.1MHz to 30MHz	19	18	
e p	Peak level	V _{DD} =5V, T _A =+25°C, conforming to SAE J 1752/3	30MHz to 130MHz	32	27	$dB\mu V$
S _{EMI}			130MHz to 1GHz	31	26	
			SAE EMI Level	4	3.5	-

Notes:

1. Data based on characterization results, not tested in production.

EMC CHARACTERISTICS (Cont'd)

14.7.3 Absolute Maximum Ratings (Electrical Sensitivity)

Based on three different tests (ESD, LU and DLU) using specific measurement methods, the product is stressed in order to determine its performance in terms of electrical sensitivity. For more details, refer to the application note AN1181.

14.7.3.1 Electro-Static Discharge (ESD)

Electro-Static Discharges (a positive then a negative pulse separated by 1 second) are applied to the pins of each sample according to each pin combination. The sample size depends on the number of supply pins in the device (3 parts*(n+1) supply pin). The Human Body Model is simulated. This test conforms to the JESD22-A114A standard.

Absolute Maximum Ratings

Symbol	Ratings	Conditions	Maximum value 1)	Unit
V _{ESD(HBM)}	Electro-static discharge voltage (Human Body Model)	T _A =+25°C	2000	٧

Notes:

1. Data based on characterization results, not tested in production.

14.7.3.2 Static and Dynamic Latch-Up

■ LU: 3 complementary static tests are required on 10 parts to assess the latch-up performance. A supply overvoltage (applied to each power supply pin) and a current injection (applied to each input, output and configurable I/O pin) are performed on each sample. This test conforms to the EIA/JESD 78 IC latch-up standard. For more details, refer to the application note AN1181.

■ DLU: Electro-Static Discharges (one positive then one negative test) are applied to each pin of 3 samples when the micro is running to assess the latch-up performance in dynamic mode. Power supplies are set to the typical values, the oscillator is connected as near as possible to the pins of the micro and the component is put in reset mode. This test conforms to the IEC1000.4-2 and SAEJ1752/3 standards. For more details, refer to the application role (N)1181.

Electrical Sensitivities

Symbol	Parameter	Conditions	Class 1)
LU	Static latch-up class	T _A =+25°C	A
DLU	Dynamic latch-up class	V_{DD} =5.5V, f_{OSC} =4MHz, T_A =+25°C	А

Notes:

1. Class description: A Class is an STMicroelectronics internal specification. All its limits are higher than the JEDEC specifications, that means when a device belongs to Class A it exceeds the JEDEC standard. B Class strictly covers all the JEDEC criteria (international standard).

14.8 COMMUNICATION INTERFACE CHARACTERISTICS

14.8.1 USB - Universal Bus Interface

USB DC Electrical Characteristics					
Parameter	Symbol	Conditions	Min.	Max.	Unit
Input Levels:					
Differential Input Sensitivity	VDI	I(D+, D-)	0.2		V
Differential Common Mode Range	VCM	Includes VDI range	0.8	2.5	V
Single Ended Receiver Threshold	VSE		1.3	2.0	V
Output Levels					
Static Output Low	VOL	RL of 1.5K ohms to 3.6v		0.3	V
Static Output High	VOH	RL of 15K ohm to V _{SS}	2.8	3.6	V
USBVCC: voltage level	USBV	V _{DD} =5v	3.00	3.60	V

Notes: RL is the load connected on the USB drivers. All the voltages are measured from the local ground potential.

Figure 43. USB: Data Signal Rise and Fall Time

USB: Full speed electrical characteristics					
Parameter	Symbol	Conditions	Min	Max	Unit
Driver characteristics:					
Rise time	tr	Note 1,CL=50 pF	4	20	ns
Fall Time	tf	Note 1, CL=50 pF	4	20	ns
Rise/ Fall Time matching	trfm	tr/tf	90	110	%
Output signal Crossover Voltage	VCRS		1.3	2.0	V

Note 1: Measured from 10% to 90% of the data signal. For more detailed informations, please refer to Chapter 7 (Electrical) of the USB specification (version 1.1).

16 DEVICE CONFIGURATION AND ORDERING INFORMATION

Each device is available for production in user programmable versions (High Density FLASH) as well as in factory coded versions (ROM/FASTROM).

ST7SCR devices are ROM versions. ST7PSCR devices are Factory Advanced Service Technique ROM (FASTROM) versions: they are factory programmed FLASH devices.

ST7FSCR FLASH devices are shipped to customers with a default content (FFh).

This implies that FLASH devices have to be configured by the customer using the Option Byte while the ROM devices are factory-configured.

16.0.1 Option Bytes

The 8 option bits from the flash are programmed through the static option byte SOB1. The description of each of these 8 bits is given below.

Static option Byte (SOB1)

OPT5= **WDGSW** *Hardware or software watchdog* This option bit selects the watchdog type.

0: Hardware (watchdog always activated)

1: Software (watchdog to be activated by software)

OPT4 = **NEST** Interrupt Controller

This bit enables the nested Interrupt Controller.

- 0: Nested interrupt controller disabled
- 1: Nested interrupt controller enabled

OPT3 = **ISOCLK** Clock source selection

- 0: Card clock is generated by the divider (48MHz/ 12 = 4MHz).
- 1: Card clock is generated by the oscillator.

OPT2 = RETRY Number of Retries for UART ISO

- 0: In case of an erroneous transfer, character is transmitted 4 times.
- 1: In case of an erroneous transfer, character is transmitted 5 times.

OPT1 = Reserved, must be kept at 1.

OPT0 = **FMP_R** Flash memory read-out protection

Readout protection, when selected provides a protection against program memory content extraction and against write access to Flash memory. This protection is based on read and a write protection of the memory it less modes and ICP mode. Frasing the option bytes when the FMP_R option is selected induce the whole user memory erasing first and the device can be reprogrammed. Refer to the ST7 Flash Programming Reference Manual and section 4.6 on page 17 for more details

0: read-out protection enabled

1 : read-out protection disabled

16.1 DEVICE ORDERING INFORMATION AND TRANSFER OF CUSTOMER CODE

Customer code is made up of the ROM contents and the list of the selected options (if any). The ROM contents are to be sent on diskette, or by electronic means, with the hexadecimal file in .S19 format generated by the development tool. All unused bytes must be set to FFh.

The selected options are communicated to STMicroelectronics using the correctly completed OPTION LIST appended. See page 94.

Refer to application note AN1635 for information on the counter listing returned by ST after code has been transferred.

The STMicroelectronics Sales Organization will be pleased to provide detailed information on contractual points.

Figure 48. Sales Type Coding Rules

Table 24. Ordering Information

Sales Type 1)	Program Memory (bytes)	RAM (bytes)	Package
ST7SCR1R4T1/xxx or ST7SCR1T1/xxx ²⁾	16K ROM		LOED64

17 IMPORTANT NOTES

17.1 UNEXPECTED RESET FETCH

If an interrupt request occurs while a "POP CC" instruction is executed, the interrupt controller does not recognise the source of the interrupt and, by default, passes the RESET vector address to the CPU.

Workaround

To solve this issue, a "POP CC" instruction must always be preceded by a "SIM" instruction.

17.2 FLASH DEVICES ONLY

The behavior described in the following section (Section 17.2.1) is present on Rev W ST7FSCR devices only.

They are identifiable:

 on the device package, by the last letter of the Trace Code marked on the device package. on the box, by the last 3 digits of the Internal Sales Type printed in the box label.

Device Identification

	Trace Code marked on device	Internal Sales Type on box label
Flash Devices:	"xxxxxxxxW"	7FSCR1R4T1\$U6
		7FSCR1E4M1\$U6

See also Figure 49.

17.2.1 SMART CARD UART AUTOMATIC REPETITION AND RETRY

A functional limitation affects the Smart Card UART automatic repetition and retry on parity error in reception and transmission mode. This failure occurrence is systematic: only 4 retries option is functional.

Figure 49Revision Marking on Box Label and Device Marking

18 REVISION HISTORY

Table 27. Revision History.

Date	Revision	Description of Changes	
11-Mar-2004	1.5	Changed labelling of Capacitors on Figure 5 & removed 3 Inserted note that C_1 and C_2 must be close to the chip on Figure 5 Changed C_{L2} from 30pF to 33pF, section 14.4.3 on page 83 Added Figure 6.Smartcard Interface Reference Application - 64-Pin LQFP Package Changed ILsink Min from 5.6mA to 5, p80, LED Pins Table Changed values in 14.5.2FLASH Memory Table For table in 14.6SMARTCARD SUPPLY SUPERVISOR ELECTRICAL CHARACTERISTICS added many references to note 1 Section 14.7.3Absolute Maximum Ratings (Electrical Sensitivity) Changed VESD Max from 1500 to 2000 V Section 14.8.1USB - Universal Bus Interface table, merged notes 1 & 2 into one note Replaced Errata sheet with Important Notes section (17IMPORTANT NOTES) Figure 14.4.3 Values changed: R_f : Min $90k\Omega$, Max $150k\Omega$; I_2 : Min $1.5mA$, Max $3.5mA$	
15-Sep-2004	2.0	Split High Current values in LED Pins table for ROM and FLASH devices Section 14.2 Clarification of read-out protection	
31-Aug-2005	3.0	Added new sales types for ROM versions based on new coding, Table 24 and in Option List Max value added for Idd WAIT, Section 14.2 Flash memory data retention increased to 40 years, Section 14.5.2 Reference made to the Flash Programming Reference Manual for Flash timing values Errata sheet content moved to Section 17 IMPORTANT NOTES	
23-Apr-2007	4.0	Addition of QFN24 package (first page, pinouts, ordering information updated) Option list updated, page 94
